

# Update on ORCA Sensitivity Study A Closer Look at the Octant Degeneracy

Martijn Jongen

Nikhef, Amsterdam

ORCA Call  
April 2015

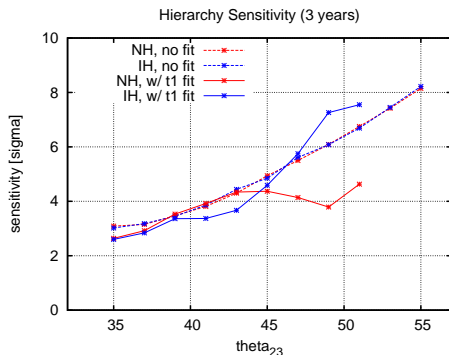

# Introduction

- ▶ Octant and hierarchy are partly degenerate
- ▶ Started investigating in response to questions about sensitivity (e.g. why is the NH line above the IH line?)
- ▶ Found very interesting behaviour

# Sensitivity as a function of $\theta_{23}$

- ▶ This looks suspicious.
- ▶ Why do we get an asymmetry between NH and IH?
- ▶ Sensitivity with fit is sometimes higher than without fit - is that even possible?
- ▶ How to interpret these results?

Median hierarchy sensitivity as a function of  $\theta_{23}$ . Dashed lines: not fitting  $\theta_{23}$ . Solid lines: fitting  $\theta_{23}$  (no prior).

# Sensitivity as a function of $\theta_{23}$

- ▶ See example LLR distributions on the right
- ▶ Distributions are still Gaussian but asymmetric

*Example: LLR distributions corresponding to  $\theta_{23} = 49^\circ$  in the plot on the previous slide.*

# Octant Fit

How well are we able to measure the octant?

- ▶ Valencia Lol model
- ▶ Fitting only hierarchy and  $\theta_{23}$  (no prior)
- ▶  $\theta_{23}$  uniformly distributed from 35 to 55 degrees
- ▶ Other parameters fixed at true values
- ▶ Note that 'measuring the octant' is meaningless at 45 degrees
- ▶ Interesting: no problem at e.g.  $\theta_{23} = 38^\circ$  but hard at e.g.  $\theta_{23} = 42^\circ$ .

*Fitted octant as a function of the true value of  $\theta_{23}$ . The error bars show  $1\sigma$  Bayesian confidence intervals for a binomial distribution.*

# Octant Fit

*Selecting only NH  
pseudo-experiments.  
More often wrong in first octant.*

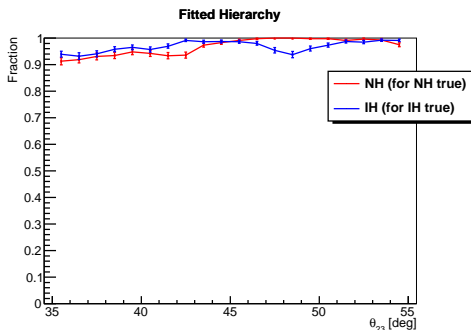

*Selecting only IH  
pseudo-experiments.  
More often wrong in second octant.*

# Hierarchy Determination

Here we see how often we fit the correct hierarchy as a function of  $\theta_{23}$

- ▶ We can already see a dependence on  $\theta_{23}$

*Fitted hierarchy as a function of the true value of  $\theta_{23}$ .*

# Hierarchy Determination

*Pseudo-experiments with*  
 $\theta_{23,fit} < 45^\circ$   
**(first octant fitted)**  
second octant IH looks like first  
octant NH

*Pseudo-experiments with*  
 $\theta_{23,fit} > 45^\circ$   
**(second octant fitted)**  
first octant NH looks like second  
octant IH

# The Explanation

- ▶ Sensitivity based on distribution of log likelihood-ratio  $R$
- ▶  $R = \log(L_{NH}/L_{IH})$   
where  $L_{NH}$  ( $L_{IH}$ ) is the likelihood of the **best fit** assuming NH (IH).
- ▶ When calculating the LLR without fitting  $\theta_{23}$  we compare NH and IH at **the same value** of  $\theta_{23}$ .
- ▶ This is no longer the case when  $\theta_{23}$  is free
- ▶ Assuming the right hierarchy the most likely  $\theta_{23}$  is usually in the **right octant**
- ▶ Assuming the wrong hierarchy often gives  $\theta_{23}$  in the **wrong octant**.
- ▶  $\Rightarrow$  we are comparing two very different numbers than before

# Fitting $\theta_{23}$ for true NH

NH pseudo-experiments. Fitted  $\theta_{23}$  when assuming NH versus the fitted  $\theta_{23}$  when assuming IH.

- ▶ Here we select only NH pseudo-experiments
- ▶ Important region 40-45 degrees (first octant)
  - ⇒ here best fit for NH and IH are in different octants
  - ⇒ expect an impact on the LLR distribution

Fitting NH pseudo-experiments assuming NH.

Fitting NH pseudo-experiments assuming IH.

# Fitting $\theta_{23}$ for true IH

IH pseudo-experiments. Fitted  $\theta_{23}$  when assuming NH versus the fitted  $\theta_{23}$  when assuming IH.

- ▶ Here we select only IH pseudo-experiments
- ▶ Important region  $>45$  degrees (second octant)
  - $\Rightarrow$  here best fit for NH and IH are in different octants
  - $\Rightarrow$  expect an impact on the LLR distribution

Fitting IH pseudo-experiments assuming NH.

Fitting IH pseudo-experiments assuming IH.

# Answers to some Big Questions

- ▶ Is this even possible?
  - ▶ Yes it is.
  - ▶ I devised a simple model that shows the same behaviour (see attachment).
  - ▶ We can get asymmetric median sensitivities
  - ▶ One of them can even be higher than the sensitivity without a fit
- ▶ Are our previous results still correct?
  - ▶ Yes they are.
  - ▶ Our results are still valid. There is nothing wrong with the method and it was applied exactly as we always have.
- ▶ Is this a problem?
  - ▶ Not really
  - ▶ But it doesn't look very pretty
  - ▶ And people will need a lot of explanation to understand it.

# Conclusions

- ▶ Good to know that these features exist
- ▶ Understand influence of  $\theta_{23}$  on sensitivity better now
- ▶ Will try to find alternative, more intuitive way to represent the sensitivity to the hierarchy and the octant
