## Outline

- Introduction
- Gluon TMDs for various target polarizations
- Gluon TMDs in the small-x limit
- Conclusion

## What is a TMD?

- A hadron correlator is parametrized in terms of transverse momentum dependent (TMD) parton distribution functions [PDFs), also called TMDs.
- A TMD is a density function in the longitudinal momentum fraction $x$ and the transverse momentum $\boldsymbol{k}_{T}$, encoding the 3D internal structure of hadrons.

parton momentum:
$k^{\mu}=x P^{\mu}+k_{T}^{\mu}+\sigma n^{\mu}$

In the small-x limit we see that

- ... the gluon TMDs either vanish or become equal.
- ... the (non-vanishing) gluon TMDs are proportional to $1 / x$ (up to resummed logs).

## Summary

- New gluon TMDs for tensor polarized targets have been introduced.

## Summary

- New gluon TMDs for tensor polarized targets have been introduced.

- The gluon-gluon correlator at $\mathrm{x}=\mathrm{O}$ reduces to the F.T. of a Wilson loop.
- Also the Wilson loop correlator can be parametrized in terms of TMDs.
- In the small-x limit the picture of gluon TMDs becomes very simple: they either vanish or become equal.
