

Results on mass composition of cosmic rays as measured with LOFAR

Tuesday, 26 July 2022 14:00 (15 minutes)

We present an updated analysis of the mass composition of cosmic rays in the 10^{17} to 10^{18} eV energy range. It is based on radio measurements of the depth of shower maximum X_{max} , done with the LOFAR telescope. We review the improvements to the reconstruction setup based on Corsika/CoREAS simulations, as well as the selection method to obtain a minimally biased X_{max} -dataset. Systematic uncertainties on X_{max} have been lowered to an estimated 7 to 9 g/cm², at a resolution of 20 g/cm² per shower. Results include estimates of the mean and standard deviation of the X_{max} -distribution. A statistical analysis at distribution level has been done as well, using a four-component model of light to heavy nuclei. It confirms our previous results showing a significant low-mass fraction in this energy range. We discuss consistency with existing results on X_{max} and mass composition.
