

# Higgs physics experimental status

Frank Filthaut

Radboud Universiteit Nijmegen / Nikhef

Disclaimers:

- ATLAS rather than CMS results (performances are in general very similar)
- not doing justice to the huge effort expended on theoretical as well as experimental side

# Contents

## Experimental aspects

- physics analysis at the LHC
- generalities of analyses in main Higgs decay modes

## Higgs boson properties

- coupling strengths
- mass
- CP nature of couplings to bosons and fermions
- decay width
- differential cross section measurements

## Searches

- probing the Higgs potential
- Beyond-the-Standard Model Higgs bosons

# Experimental aspects

# The path to the energy frontier: the LHC

LHC built to discover a SM Higgs boson of any mass in the range  
 $100 \text{ GeV} \lesssim m_H < 1 \text{ TeV}$

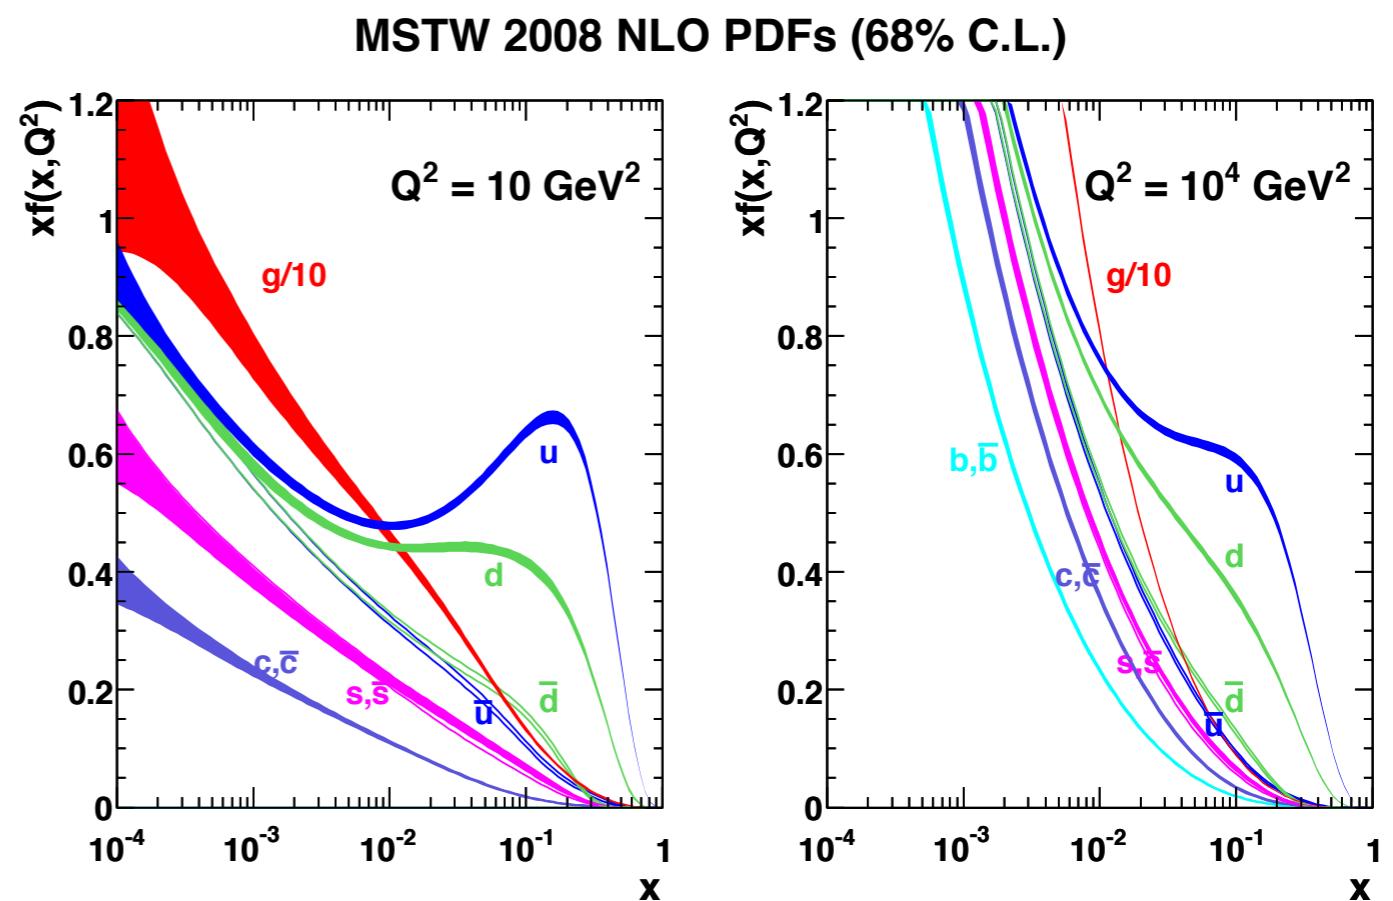

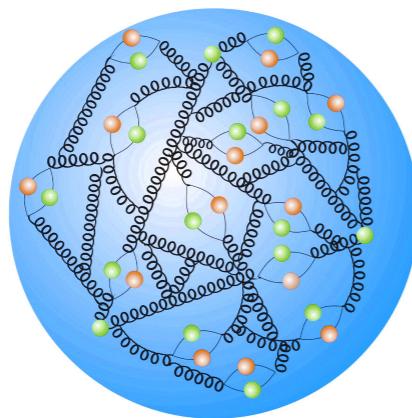

- or to discover BSM physics — “no-lose theorem”

Protons are the standard vehicle for the highest-energy colliders:

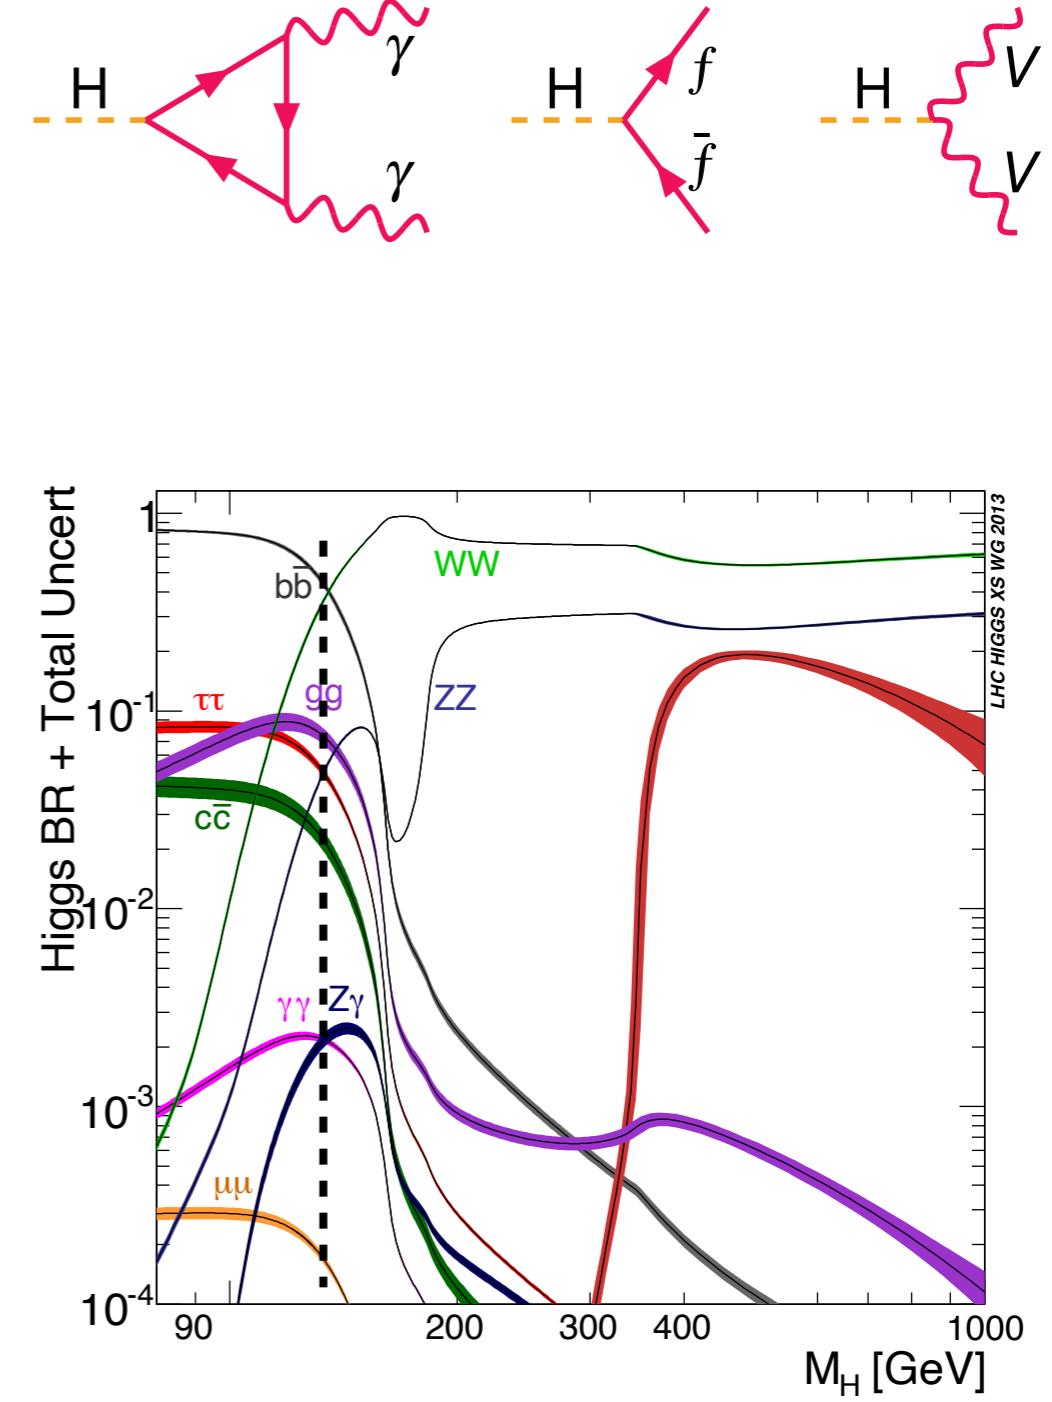

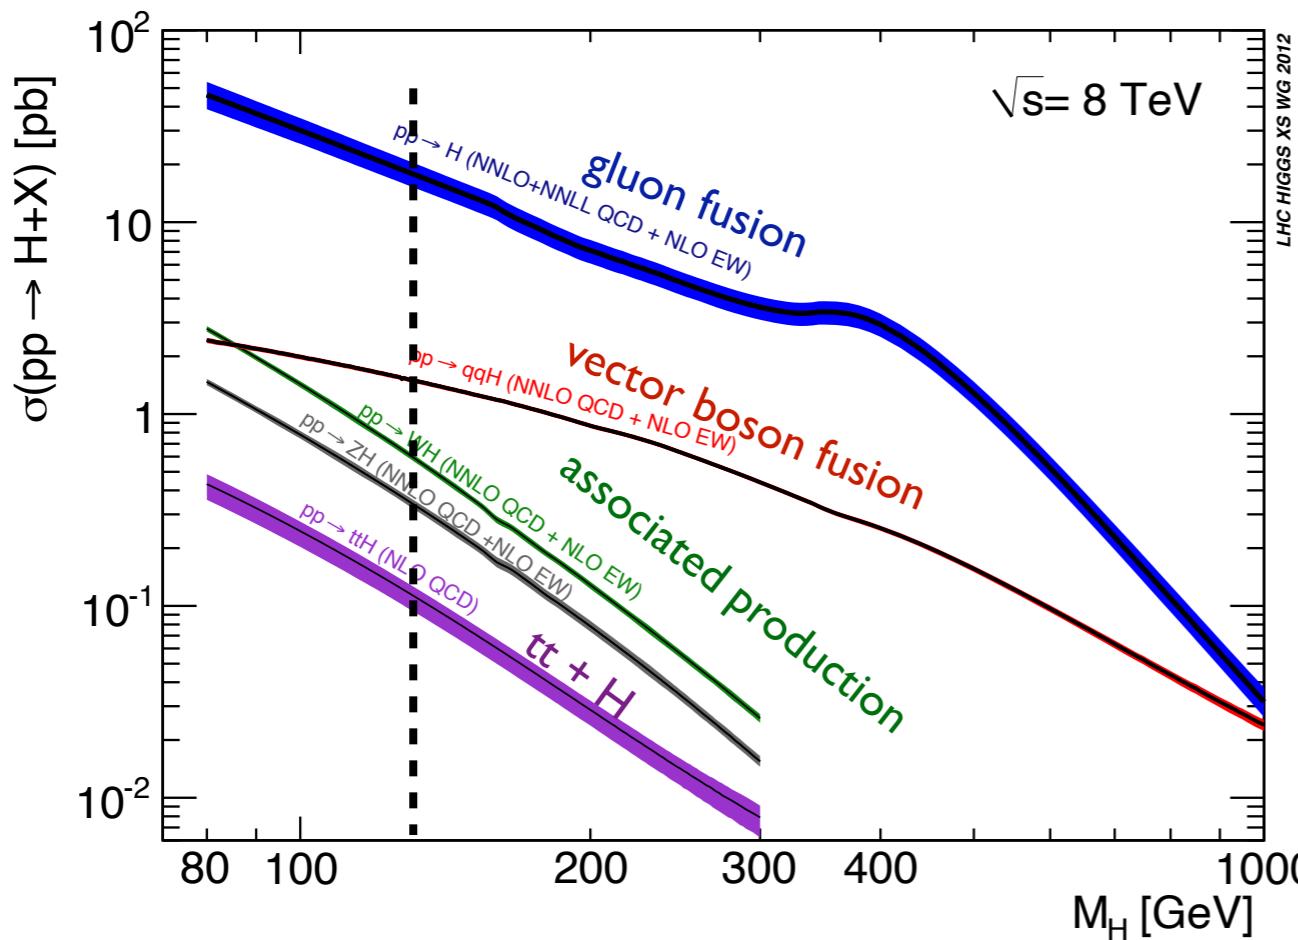

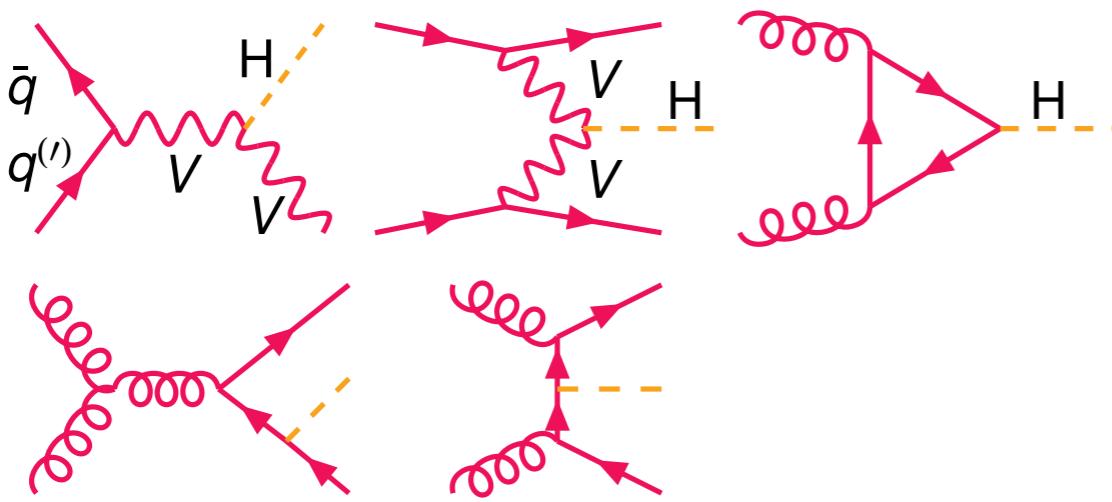

- heavy (or at least  $m_p \gg m_e$ )  $\rightarrow$  synchrotron radiation not an issue at  $\sqrt{s} = 14 \text{ TeV}$
- protons are stable  $\rightarrow$  high intensity possible (nominal  $\mathcal{L} = 10^{34} \text{ cm}^{-2}\text{s}^{-1}$ )

Protons are a rich source of quarks & gluons

- both a bliss and a curse!
- $\sigma_{\text{tot}} \sim 10^{10} \sigma(H)$

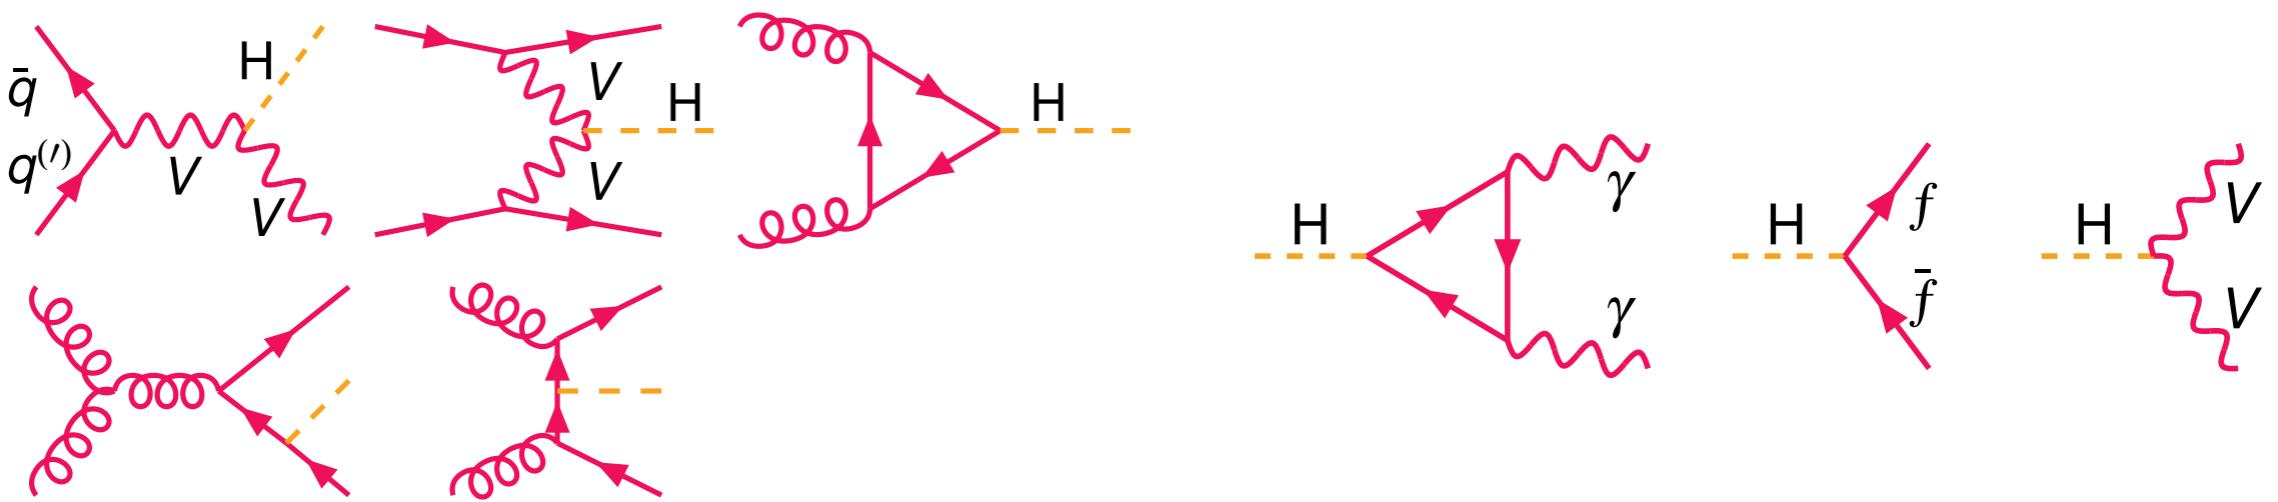

# Higgs boson production & decay

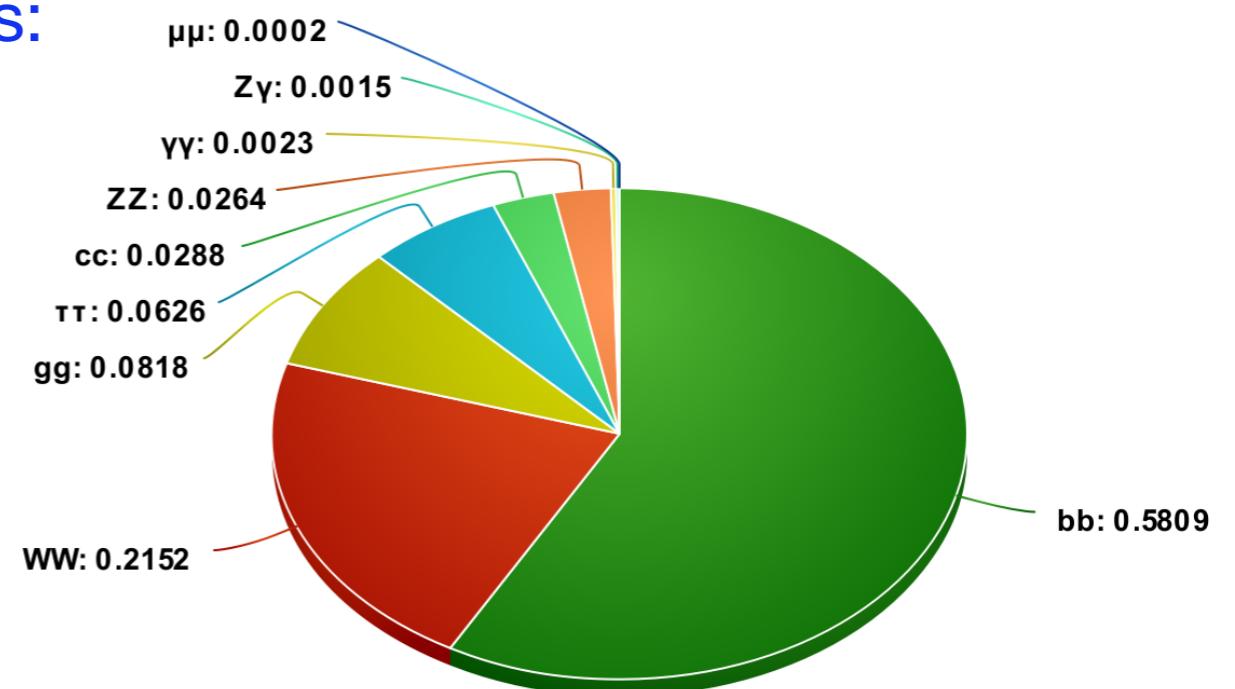

figures from <https://twiki.cern.ch/twiki/bin/view/LHCPhysics/CrossSections>

# Higgs boson production & decay

Different modes probe different couplings:

- production:
  - $ggF, t\bar{t}H$ : coupling to fermions
  - $VBF, VH$ : coupling to  $W, Z$
- decay:
  - clear for decays to  $f\bar{f}, VV$
  - $H \rightarrow \gamma\gamma$ : coupling to both  $W$  boson and fermions

For  $m_H = 125$  GeV:  $\Gamma = 4.1$  MeV

# Detection techniques

Always start from “stable” particles!

- $e^\pm, \mu^\pm, \gamma$
- charged particles (mostly  $\pi^\pm$ )
- energy deposits in calorimeters

ATLAS animation,  
but techniques are  
general for high-energy  
collider experiments

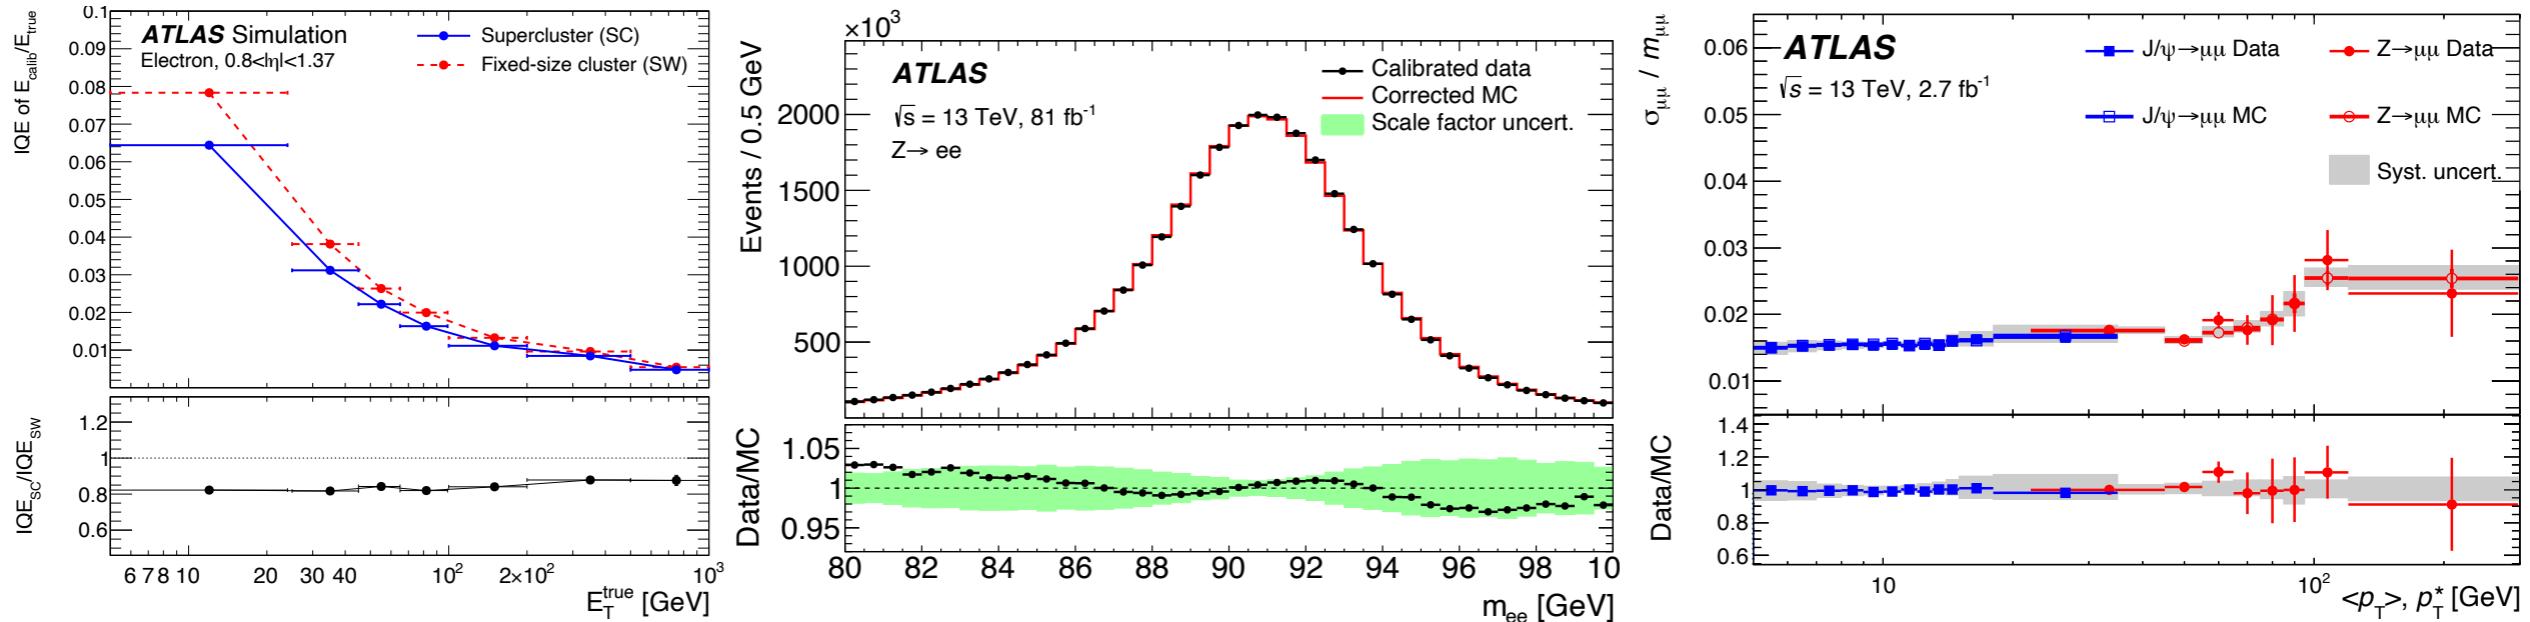

Beyond these:

- jets: collimated streams of hadrons, representative of high-energy  $q/\bar{q}/g$ 
  - LHC: anti- $k_t$  algorithm (ATLAS:  $R = 0.4$ )
- $b$ -quark jets: identified from  $\tau(b \text{ hadrons}) \sim 1.5 \text{ ps}$ ; decays reconstructed using tracking information (ATLAS: for  $\epsilon_b = 70\%$ :  $\epsilon_c = 20\%$ ,  $\epsilon_l = 0.2\%$ )
- $\tau$  leptons:  $\tau_\tau \sim 300 \text{ fs}$ ; hadronic decays  $\rightarrow$  narrow jets (difficult to distinguish from jets)
- $\nu$ : seen as apparent lack of momentum balance in the transverse plane
  - no constraint possible along the beam direction

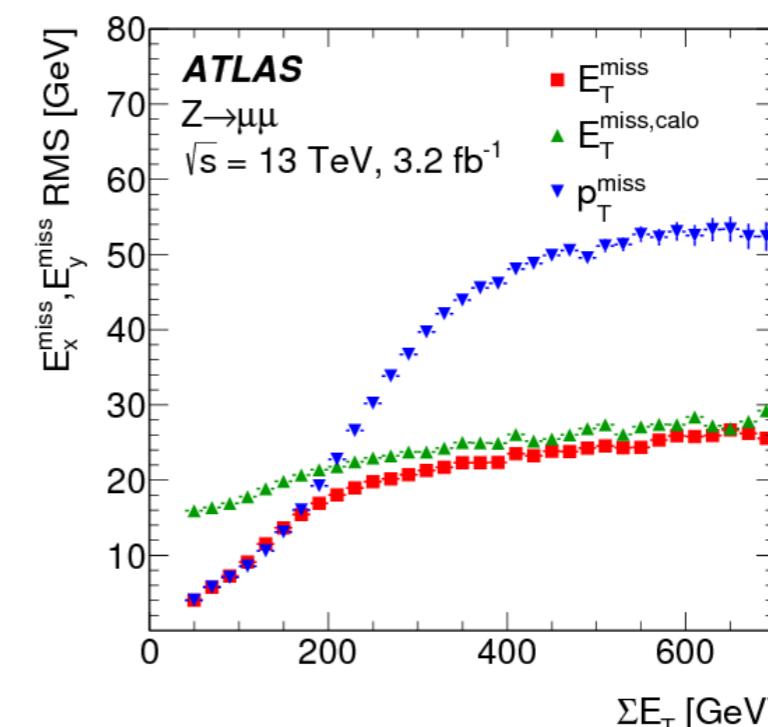

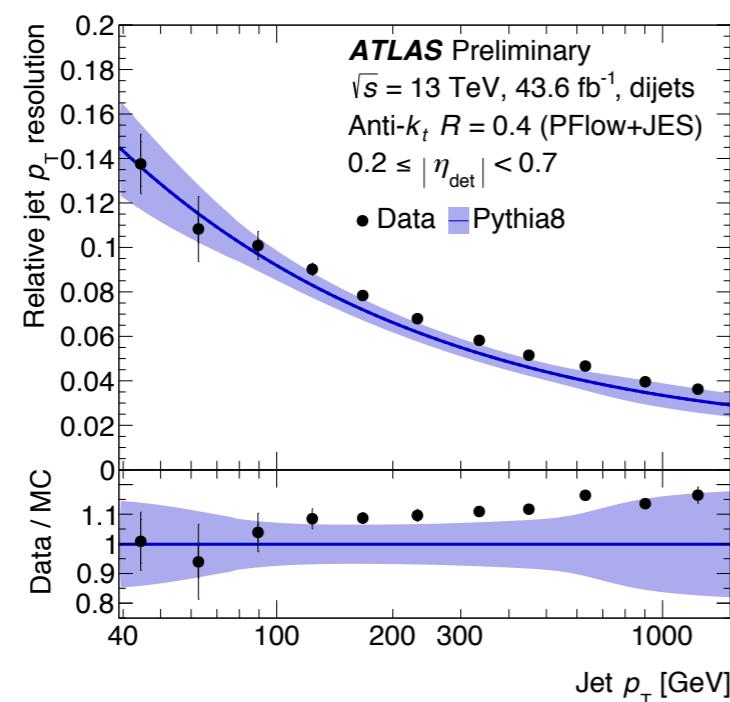

# Resolutions: general guideline

$e^\pm, \mu^\pm, \gamma$ : excellent momentum resolution, “easy” to identify

- but beware of HF decays, jets fragmenting to  $\pi^0$

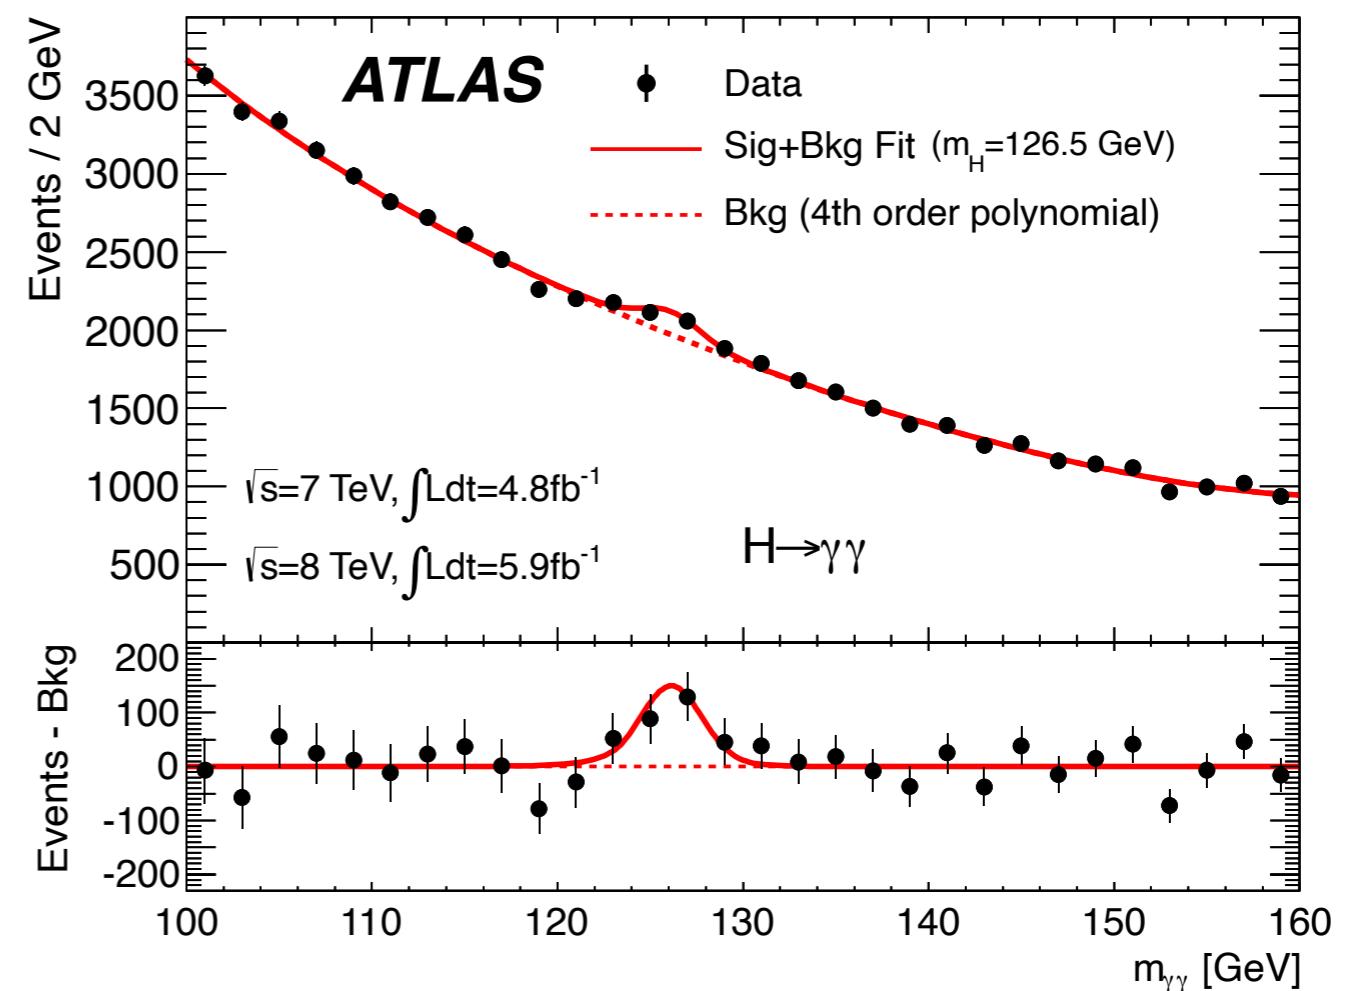

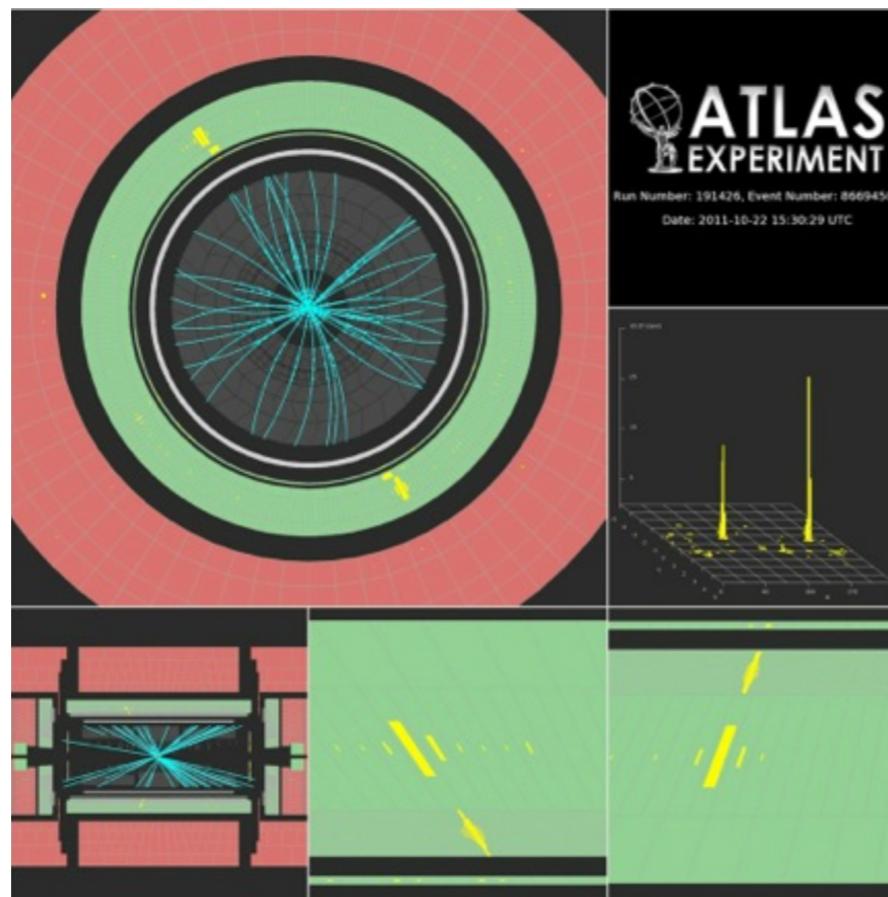

jets: resolution significantly worse; missing  $E_T$ : relatively poor

# $H \rightarrow \gamma\gamma$

Typically, large (or at least substantial) background from  $\gamma + \text{jet}$  and  $\text{jet} + \text{jet}$  processes

- need a statistical background subtraction
- common to all production modes

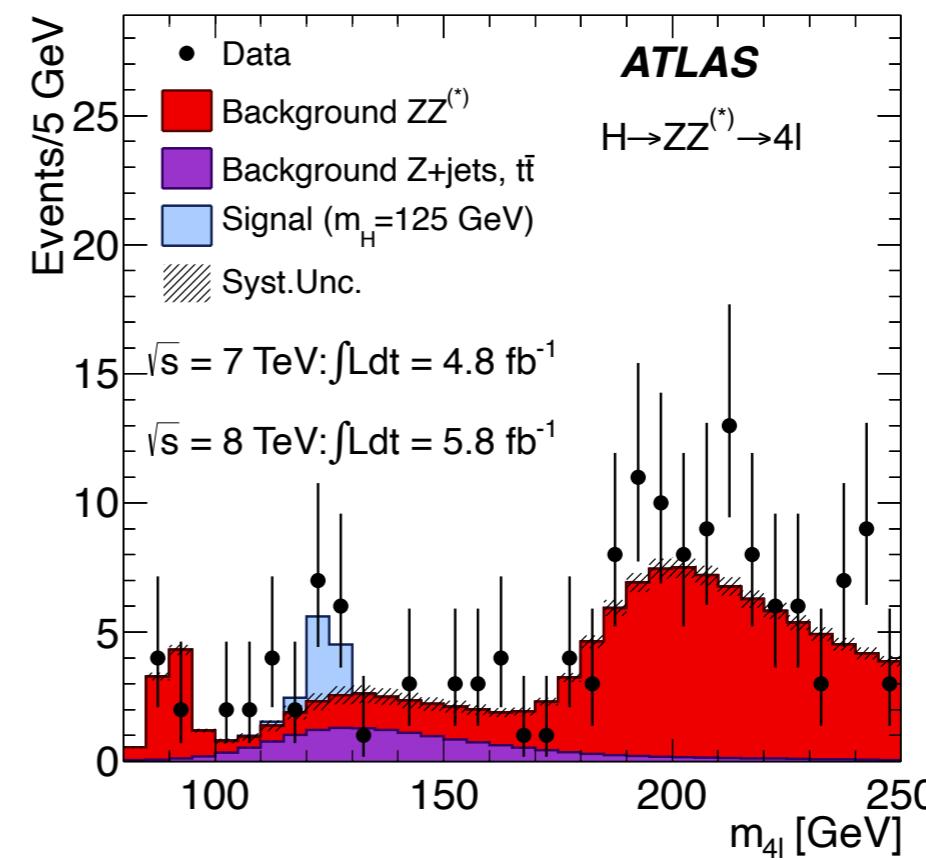

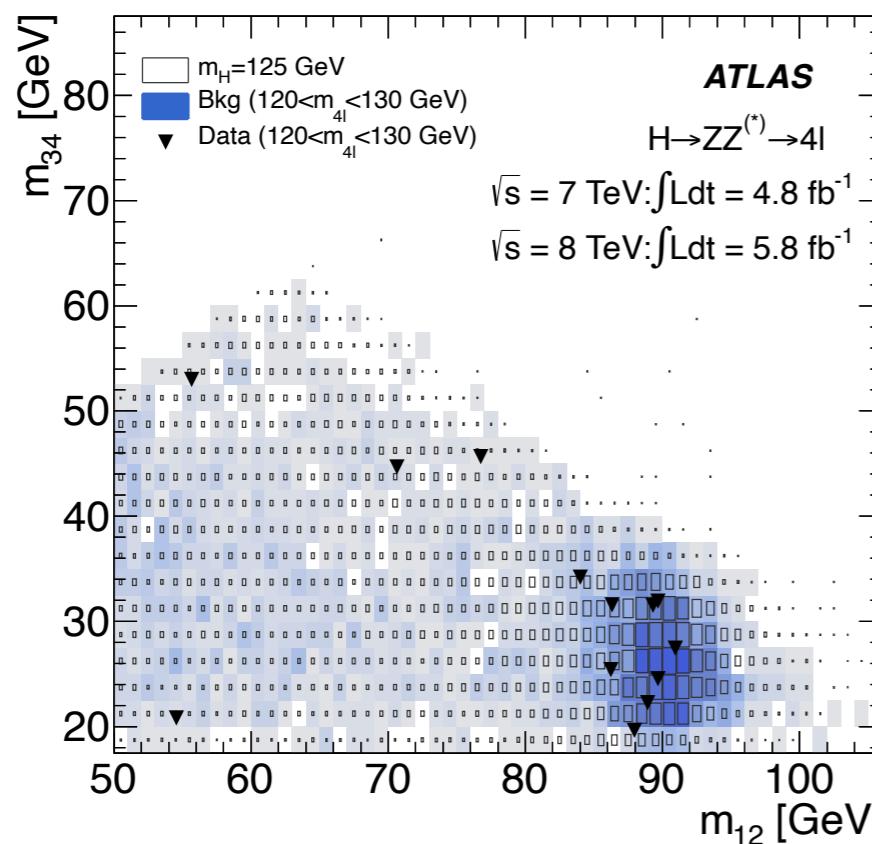

Note: observation of this decay mode precludes spin-1 hypothesis

- Landau-Yang theorem

# $H \rightarrow ZZ \rightarrow 4 \text{ leptons } (eeee, ee\mu\mu, \mu\mu\mu)$

“Golden mode”: select four isolated electrons / muons

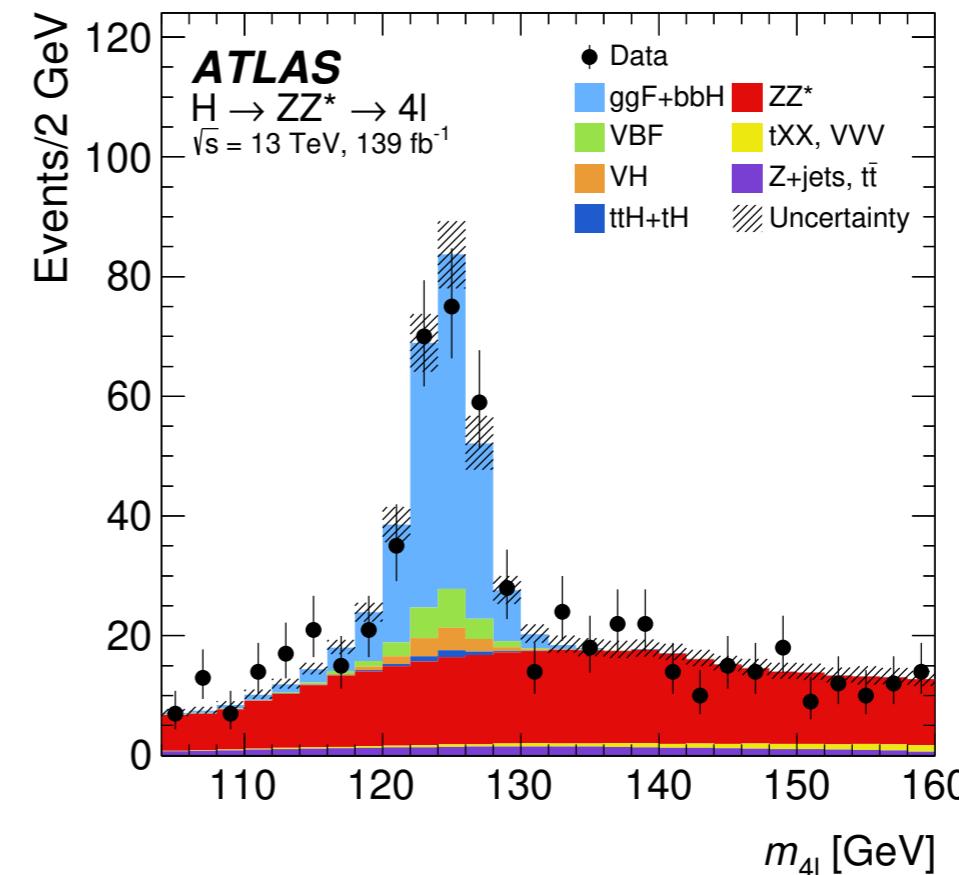

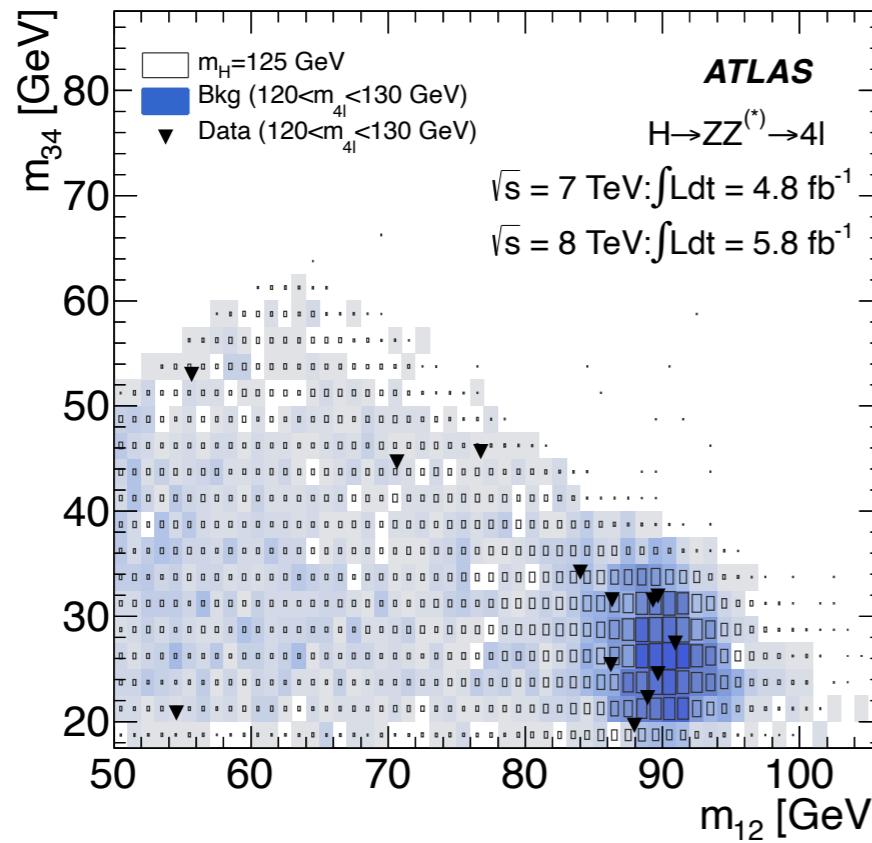

- drawback: low  $Z \rightarrow \ell^+ \ell^-$  branching fractions (3.4%)
- one off-shell  $Z$  boson  $\rightarrow$  one pair of very soft leptons ( $p_T(\ell) > 6 \text{ GeV}$ )
  - control regions to constrain background normalisations
- irreducible  $ZZ^{(*)}$  background not an issue due to good mass resolution

# $H \rightarrow ZZ \rightarrow 4 \text{ leptons } (eeee, ee\mu\mu, \mu\mu\mu\mu)$

“Golden mode”: select four isolated electrons / muons

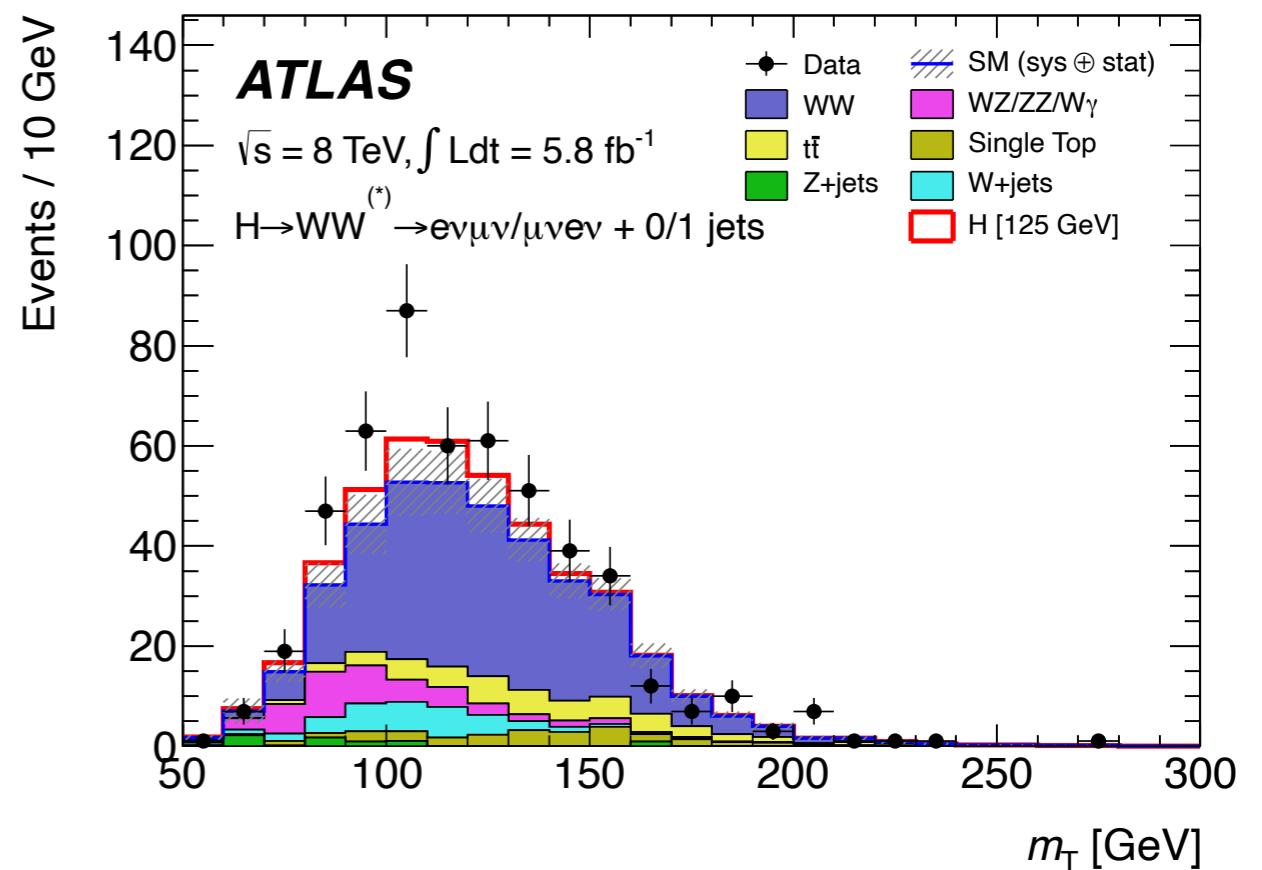

- drawback: low  $Z \rightarrow \ell^+ \ell^-$  branching fractions (3.4%)
- one off-shell  $Z$  boson  $\rightarrow$  one pair of very soft leptons ( $p_T(\ell) > 6 \text{ GeV}$ )
  - control regions to constrain background normalisations
- irreducible  $ZZ^{(*)}$  background not an issue due to good mass resolution

$$H \rightarrow W^+W^- \rightarrow \ell^+\nu_\ell\ell'^-\bar{\nu}_{\ell'}$$

Two escaping  $\nu \rightarrow$  mass reconstruction not possible

- but some sensitivity retained:  $m_T = \sqrt{(E_T^{\ell\ell} + E_T^{\text{miss}})^2 - |\mathbf{p}_T^{\ell\ell} + \mathbf{p}_T^{\text{miss}}|^2}$ ,  $E_T^{\ell\ell} = \sqrt{|\mathbf{p}_T^{\ell\ell}|^2 + m_{\ell\ell}^2}$

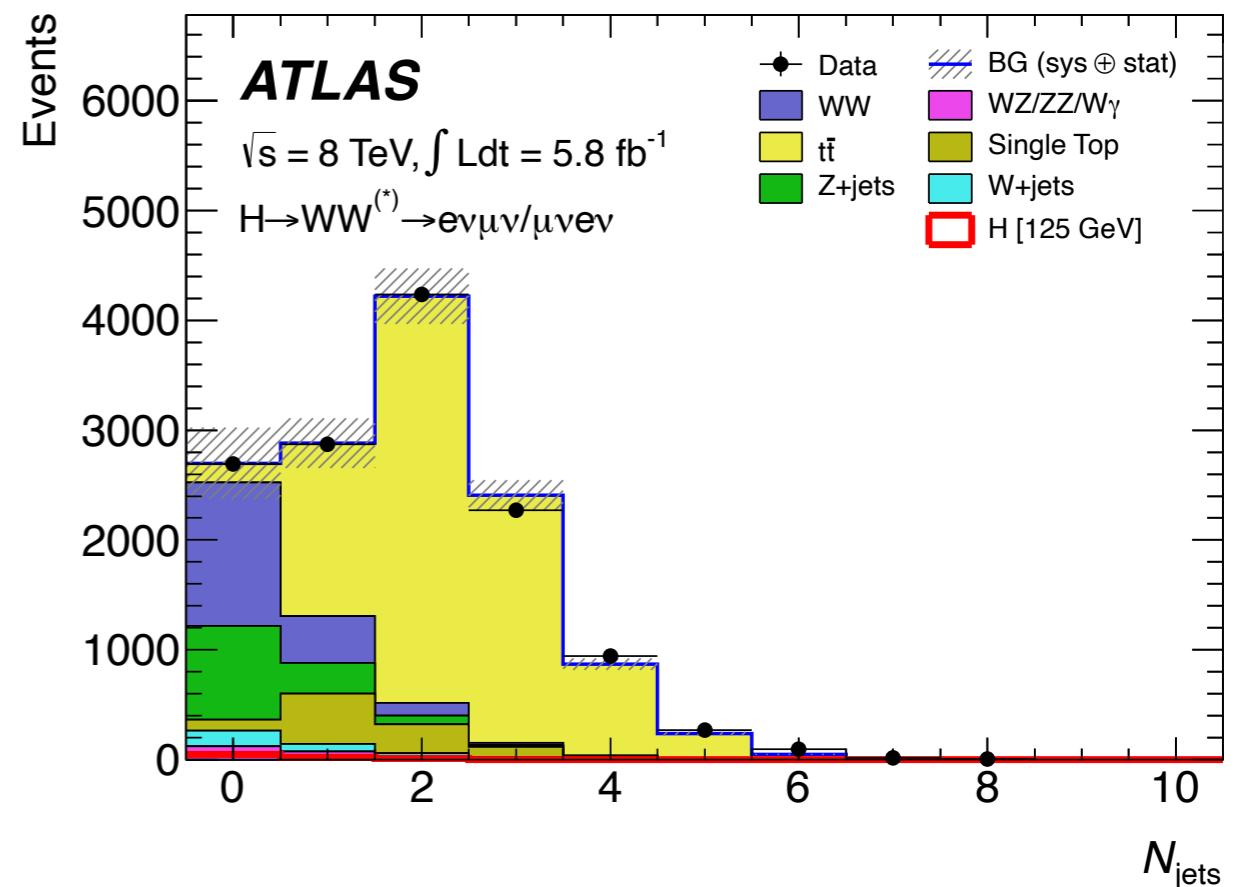

$$H \rightarrow W^+W^- \rightarrow \ell^+\nu_\ell\ell'^-\bar{\nu}_{\ell'}$$

Two escaping  $\nu \rightarrow$  mass reconstruction not possible

- but some sensitivity retained:  $m_T = \sqrt{(E_T^{\ell\ell} + E_T^{\text{miss}})^2 - |\mathbf{p}_T^{\ell\ell} + \mathbf{p}_T^{\text{miss}}|^2}$ ,  $E_T^{\ell\ell} = \sqrt{|\mathbf{p}_T^{\ell\ell}|^2 + m_{\ell\ell}^2}$

Large branching fraction (22%), but large irreducible ( $W^+W^-$ ) and reducible backgrounds ( $t\bar{t}$ ,  $W$ +jets, ...)

- use of control regions critical
- jet multiplicity dependent  $\rightarrow$   
analysis carried out in separate  
 $0, 1, \geq 2$  jet multiplicity bins
  - substantial uncertainties related to QCD radiative corrections

$$H \rightarrow W^+W^- \rightarrow \ell^+\nu_\ell\ell'^-\bar{\nu}_{\ell'}$$

Two escaping  $\nu$   $\Rightarrow$  mass reconstruction not possible

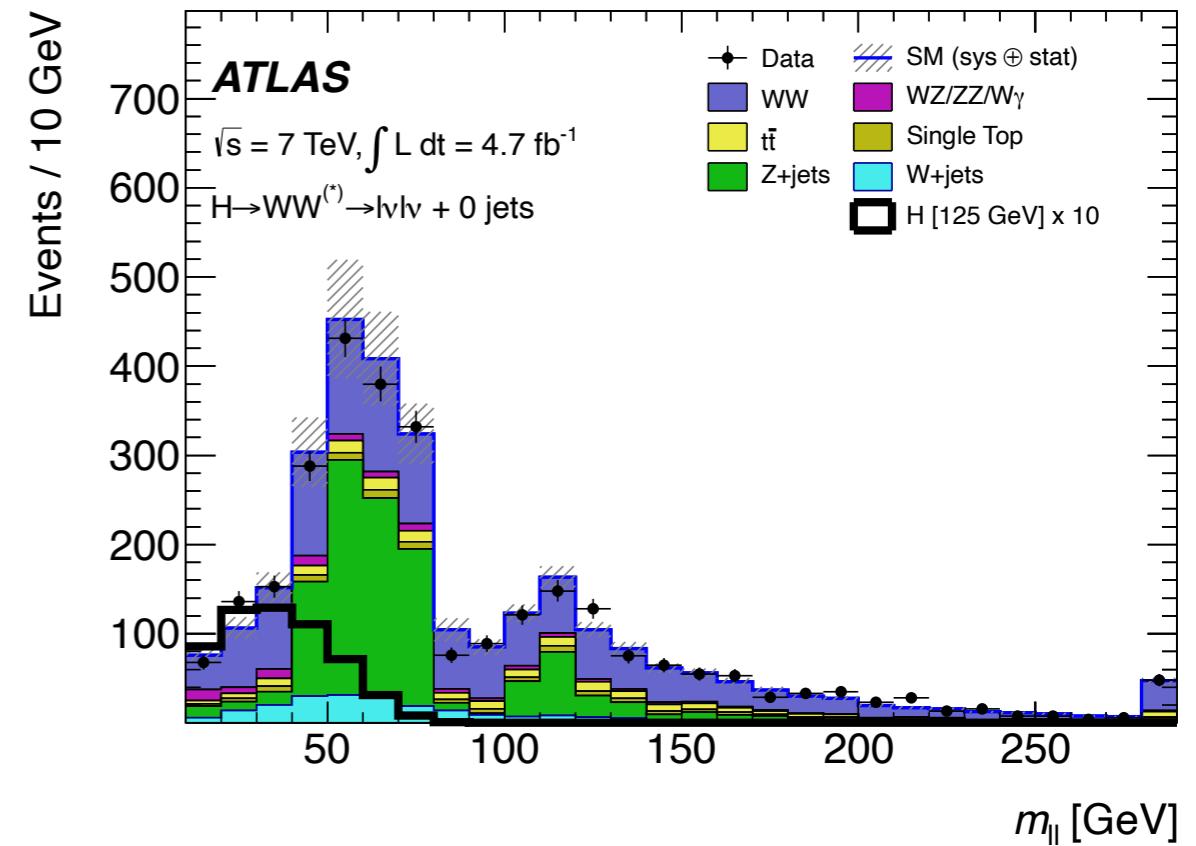

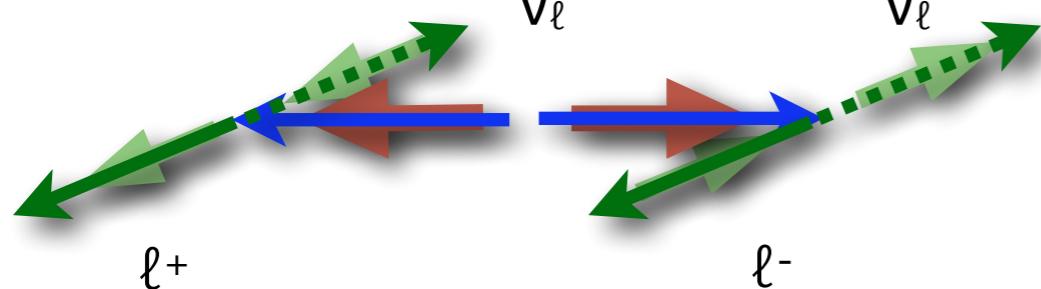

- but some sensitivity retained:  $m_T = \sqrt{(E_T^{\ell\ell} + E_T^{\text{miss}})^2 - |\mathbf{p}_T^{\ell\ell} + \mathbf{p}_T^{\text{miss}}|^2}$ ,  $E_T^{\ell\ell} = \sqrt{|\mathbf{p}_T^{\ell\ell}|^2 + m_{\ell\ell}^2}$

Large branching fraction (22%), but large irreducible ( $W^+W^-$ ) and reducible backgrounds ( $t\bar{t}$ ,  $W$ +jets, ...)

- use of control regions critical
- jet multiplicity dependent  $\Rightarrow$   
analysis carried out in separate  
0,1,  $\geq 2$  jet multiplicity bins
  - substantial uncertainties related to QCD radiative corrections

The Higgs boson's (expected)  
spin-0 nature is (typically) exploited

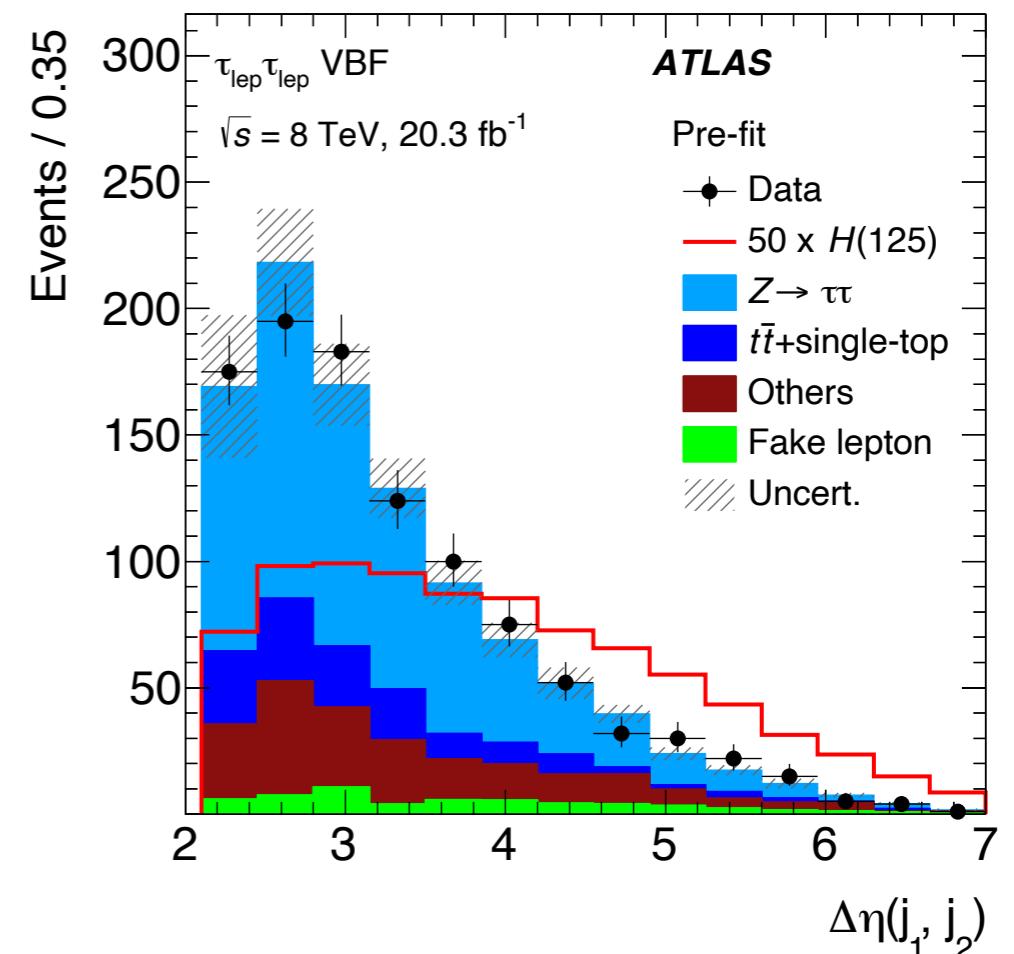

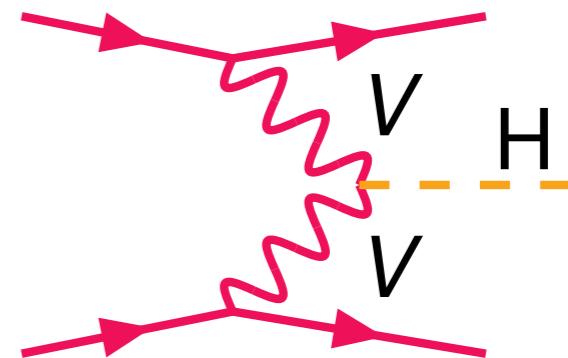

- small  $m(\ell^+\ell'^-)$  and  $\Delta\phi(\ell^+\ell'^-)$

$$H \rightarrow \tau^+ \tau^-$$

Analyses complicated by many  
 $\tau$  decay modes and escaping  $\nu$

- poor mass resolution
  - in ggF, suffer from large  $Z \rightarrow \tau^+ \tau^-$  background
  - highest sensitivity achieved in VBF production mode

large  $|y| \rightarrow \sim$  along beam direction

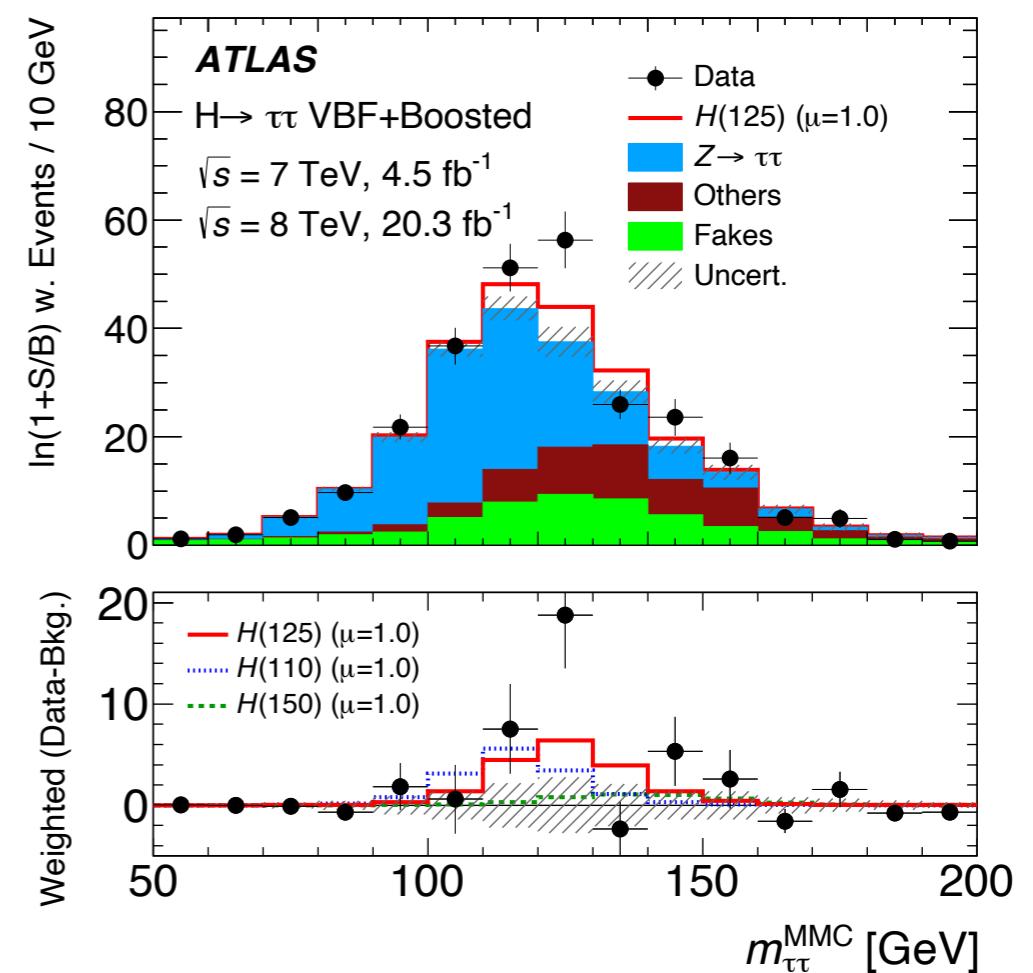

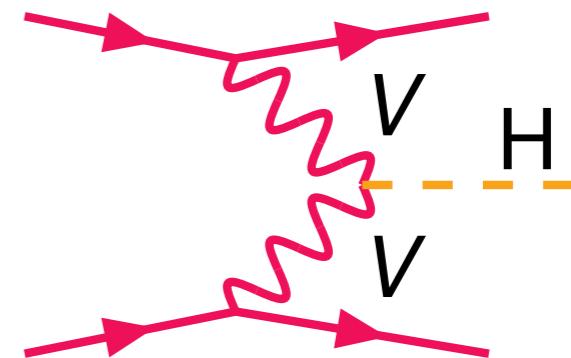

- rapidity differences invariant under boost along beam direction

$$y \equiv \frac{1}{2} \ln \left( \frac{E - p_z}{E + p_z} \right)$$

# $H \rightarrow \tau^+ \tau^-$

Analyses complicated by many  $\tau$  decay modes and escaping  $\nu$

- poor mass resolution
  - ➡ in ggF, suffer from large  $Z \rightarrow \tau^+ \tau^-$  background
  - ➡ highest sensitivity achieved in VBF production mode
- using  $m_\tau$  as a constraint allows to mitigate resolution effects somewhat

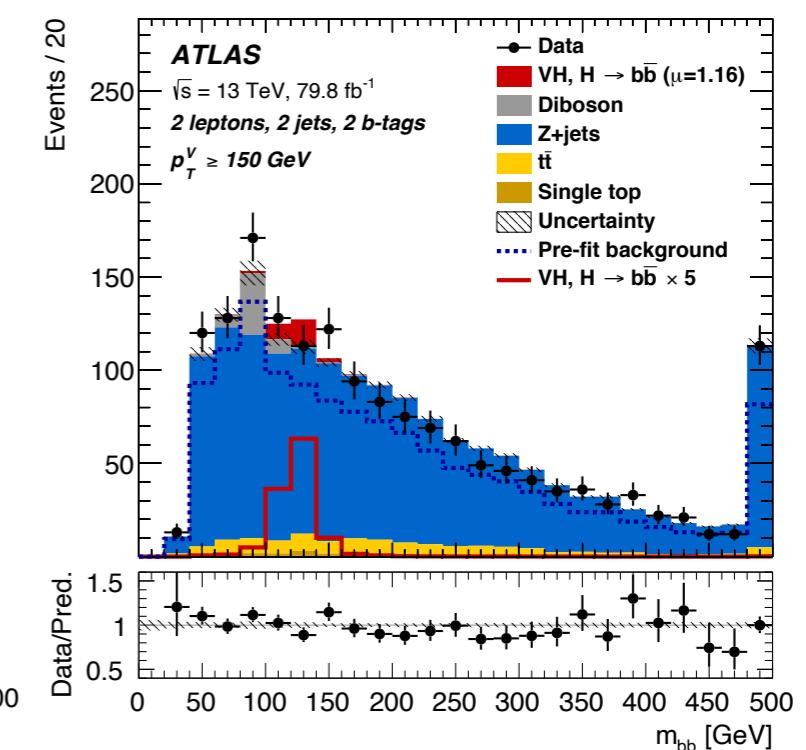

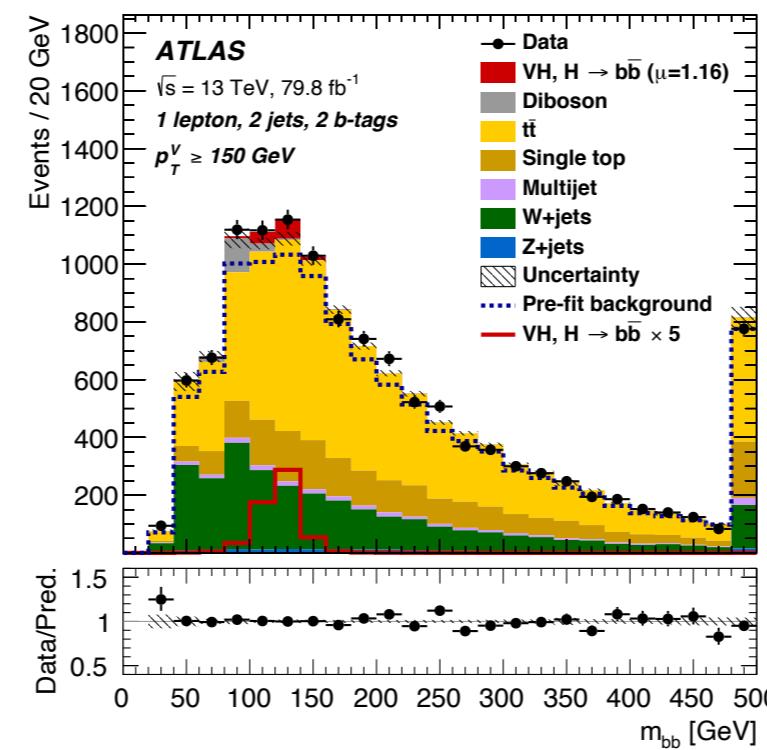

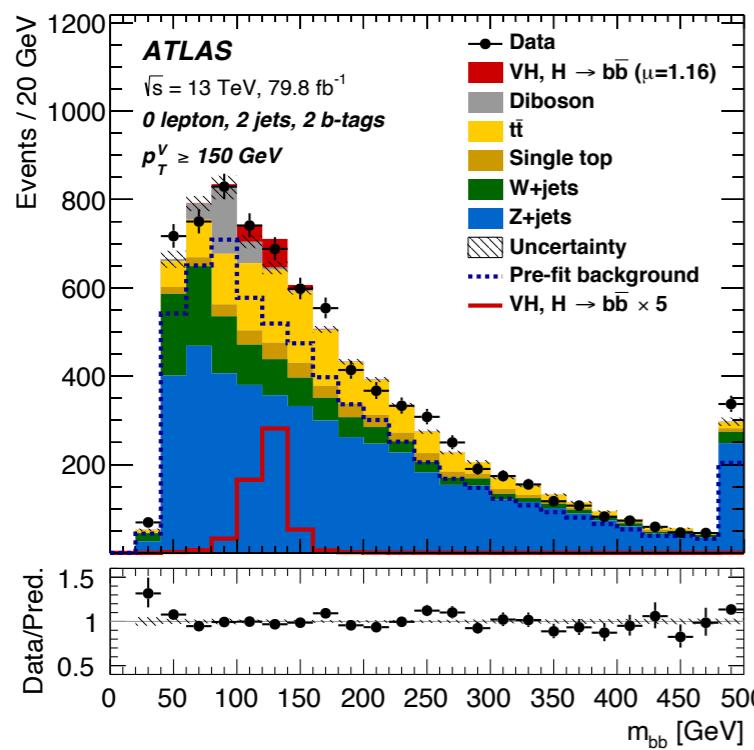

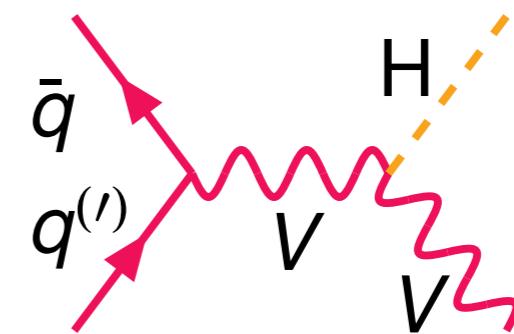

# $H \rightarrow b\bar{b}$

Overwhelming background from  $b\bar{b}$  through strong interaction  
 ➡ only observed in associated production so far

- $Z \rightarrow \ell^+ \ell^-, \nu \bar{\nu}; W \rightarrow \ell \nu$

Sensitivity limited by dominant irreducible ( $W/Z + b\bar{b}$ ) and reducible ( $t\bar{t}$ ) backgrounds

- multivariate analysis techniques necessary (also used in other Higgs analyses)
- binning in jet and  $b$ -tag multiplicity

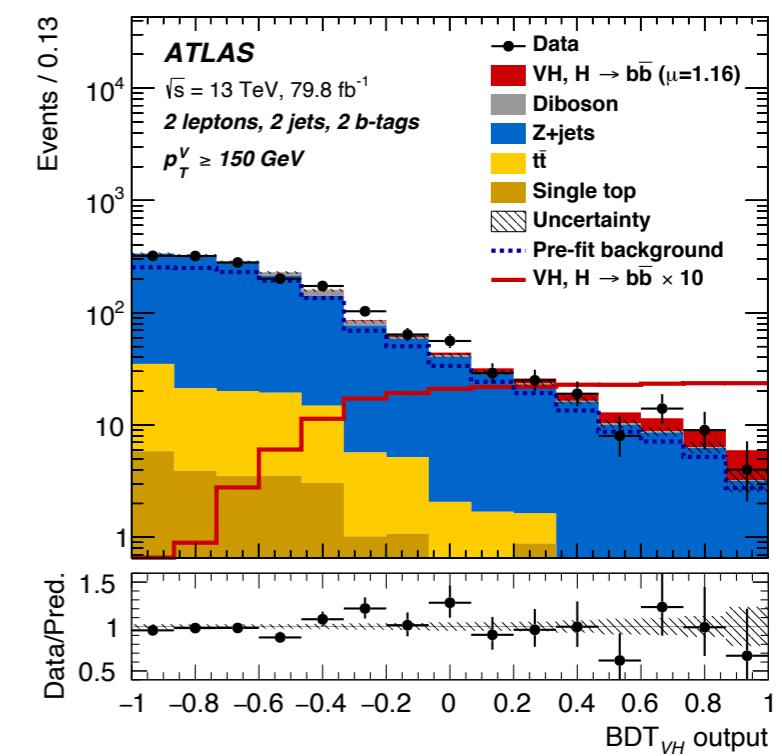

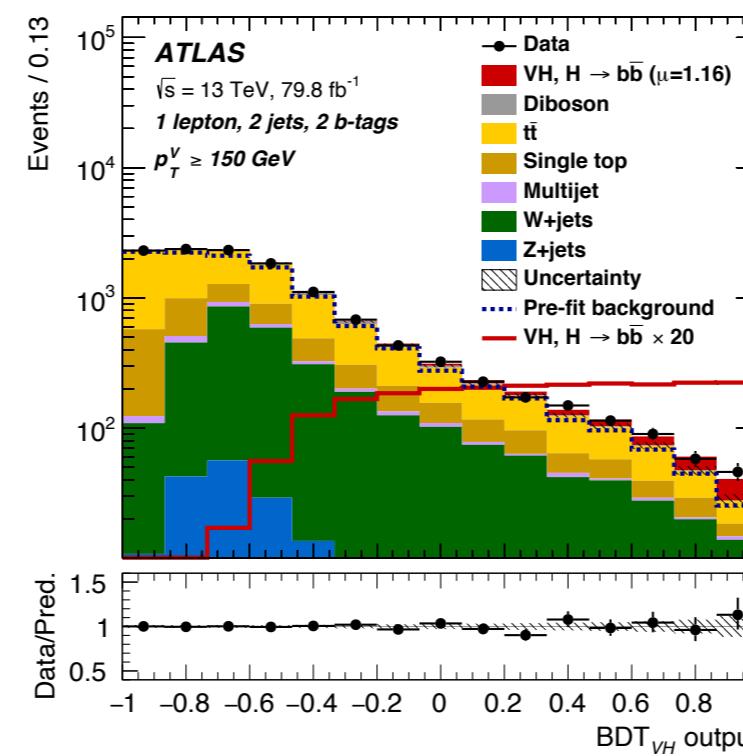

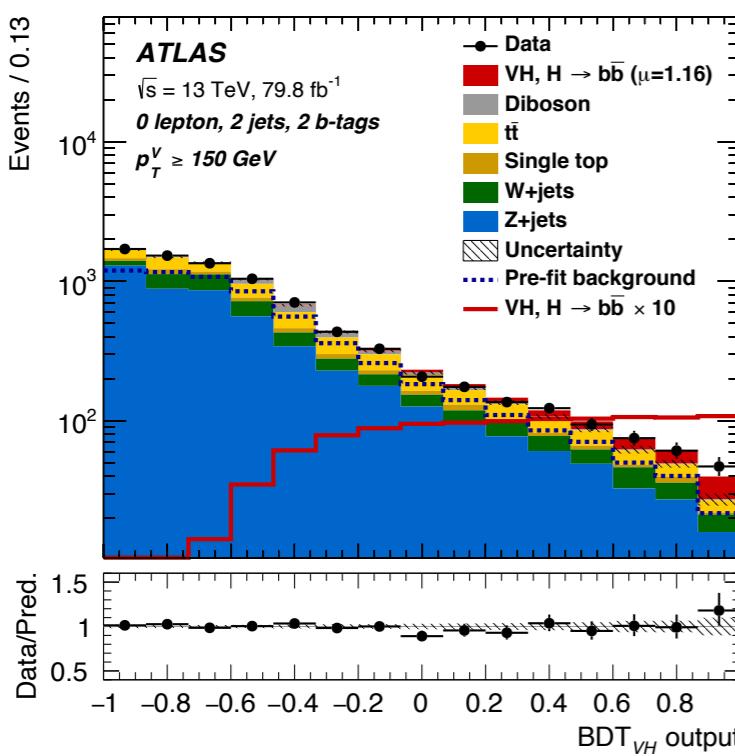

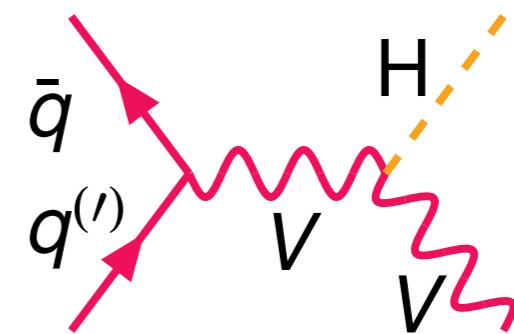

# $H \rightarrow b\bar{b}$

Overwhelming background from  $b\bar{b}$  through strong interaction  
 ➡ only observed in associated production so far

- $Z \rightarrow \ell^+ \ell^-, \nu \bar{\nu}; W \rightarrow \ell \nu$

Sensitivity limited by dominant irreducible ( $W/Z + b\bar{b}$ ) and reducible ( $t\bar{t}$ ) backgrounds

- multivariate analysis techniques necessary (also used in other Higgs analyses)
- binning in jet and  $b$ -tag multiplicity

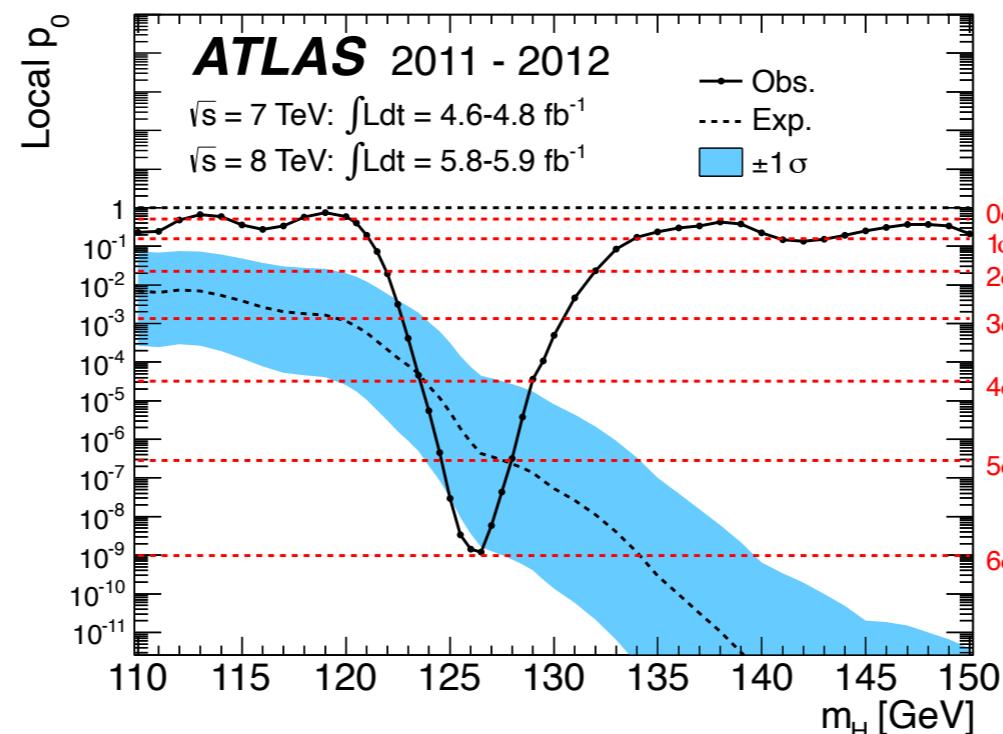

# Statistical analysis

Basic approach: use (binned or unbinned) likelihood ratio (“profile LH”)

$$\lambda(\mu) = L\left(\mu, \hat{\vec{\theta}}(\mu)\right) / L\left(\hat{\mu}, \hat{\vec{\theta}}\right)$$

- $\mu$ : assumed signal strength
  - also other parameters of interest possible
- $\vec{\theta}$ : nuisance parameters parameterising effect of systematic uncertainties on predictions
- per channel or combined (allowing for proper accounting of correlations)
- multiple  $\mu$  parameters when relaxing assumptions

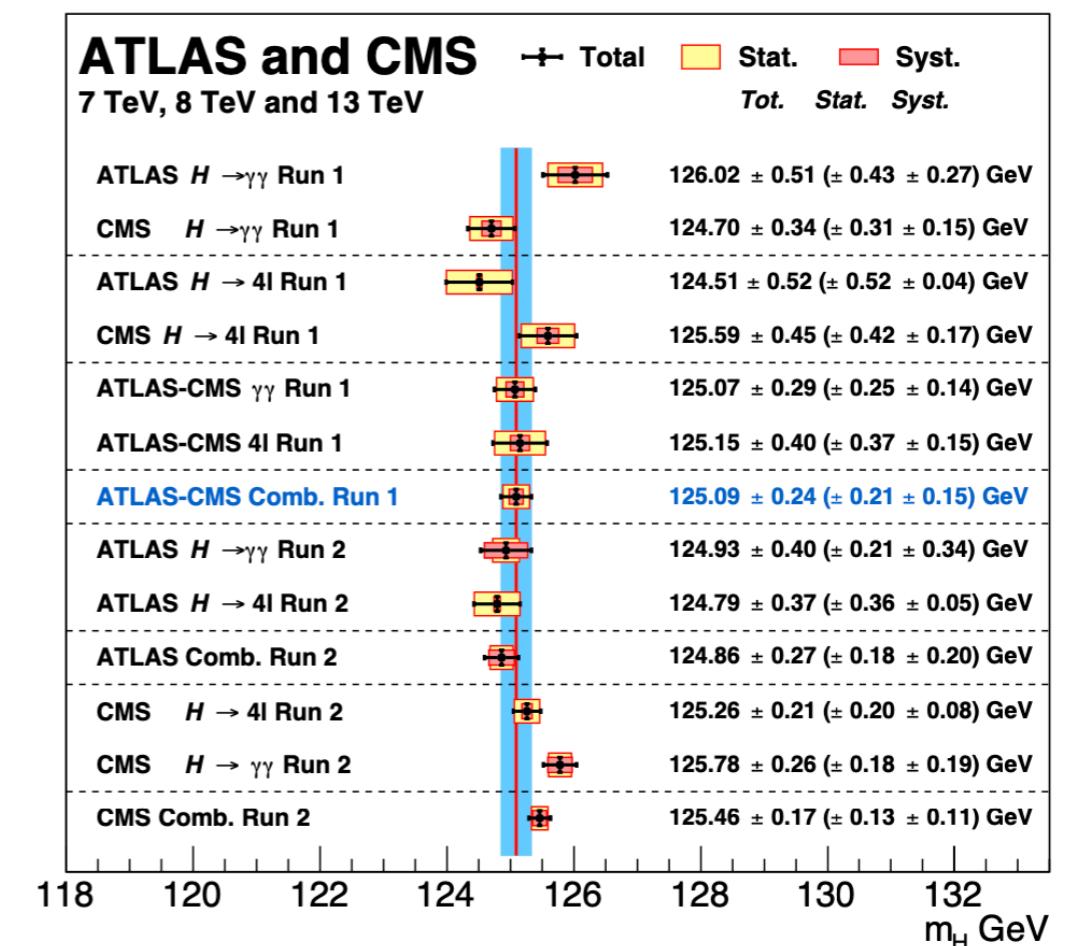

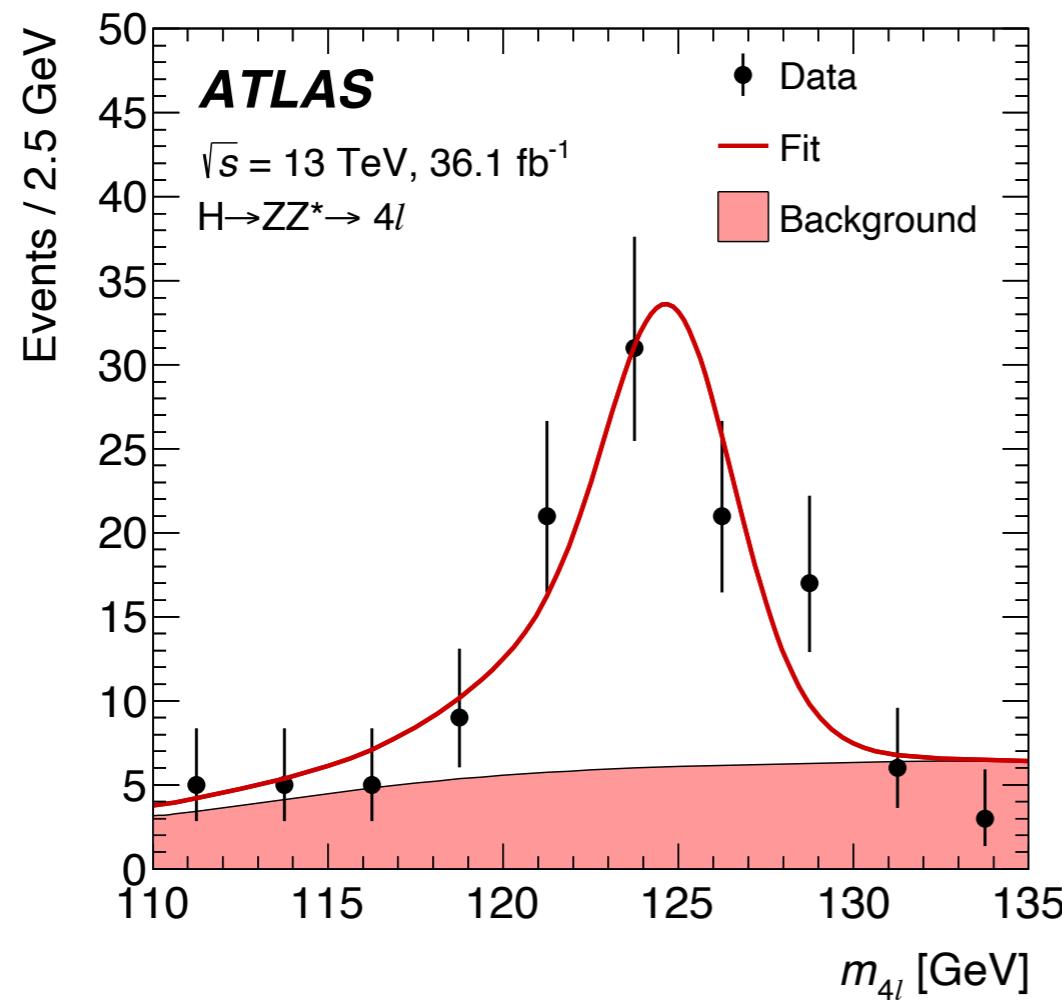

# Higgs boson properties

# Higgs boson mass

Exploit high-resolution channels ( $H \rightarrow \gamma\gamma, H \rightarrow \ell^+\ell^-\ell'^+\ell'^-$ )

- relative precision approaching 1%

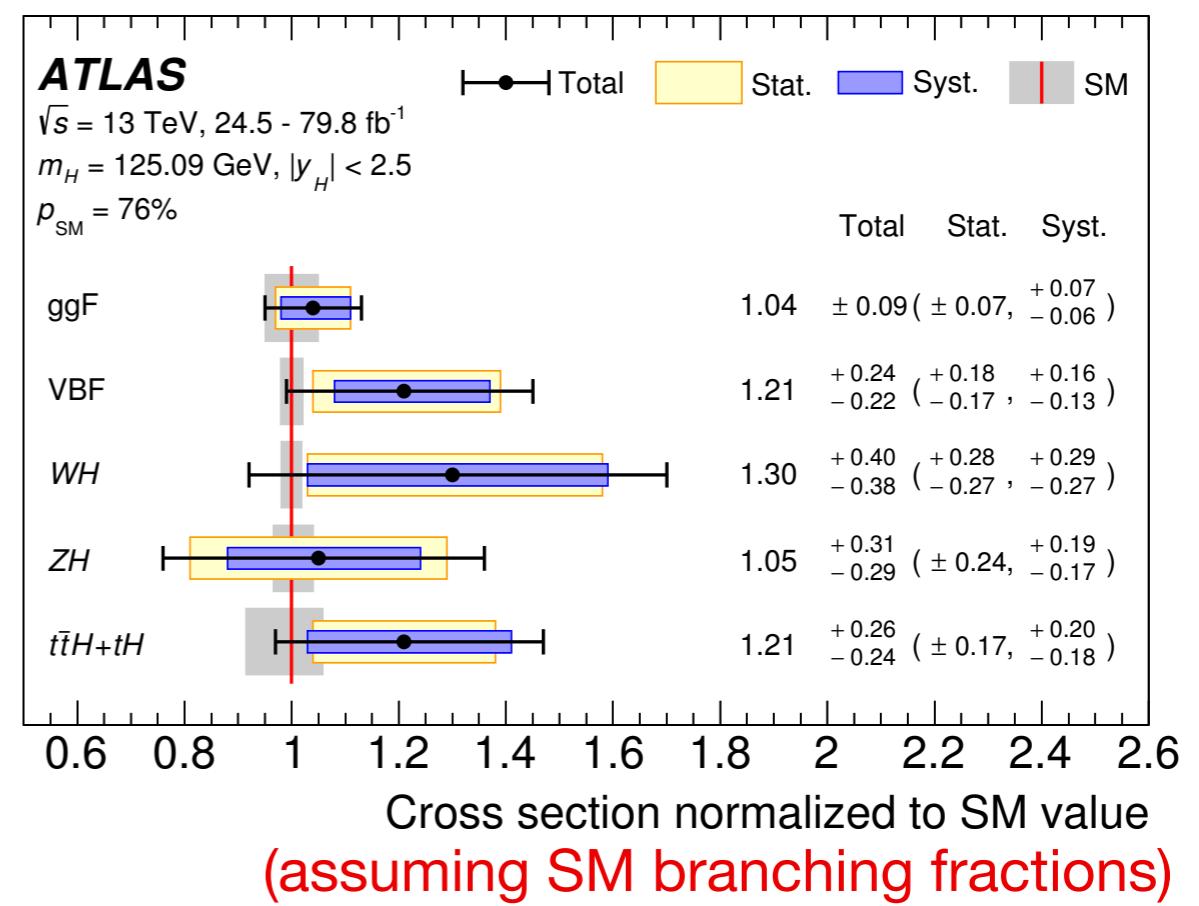

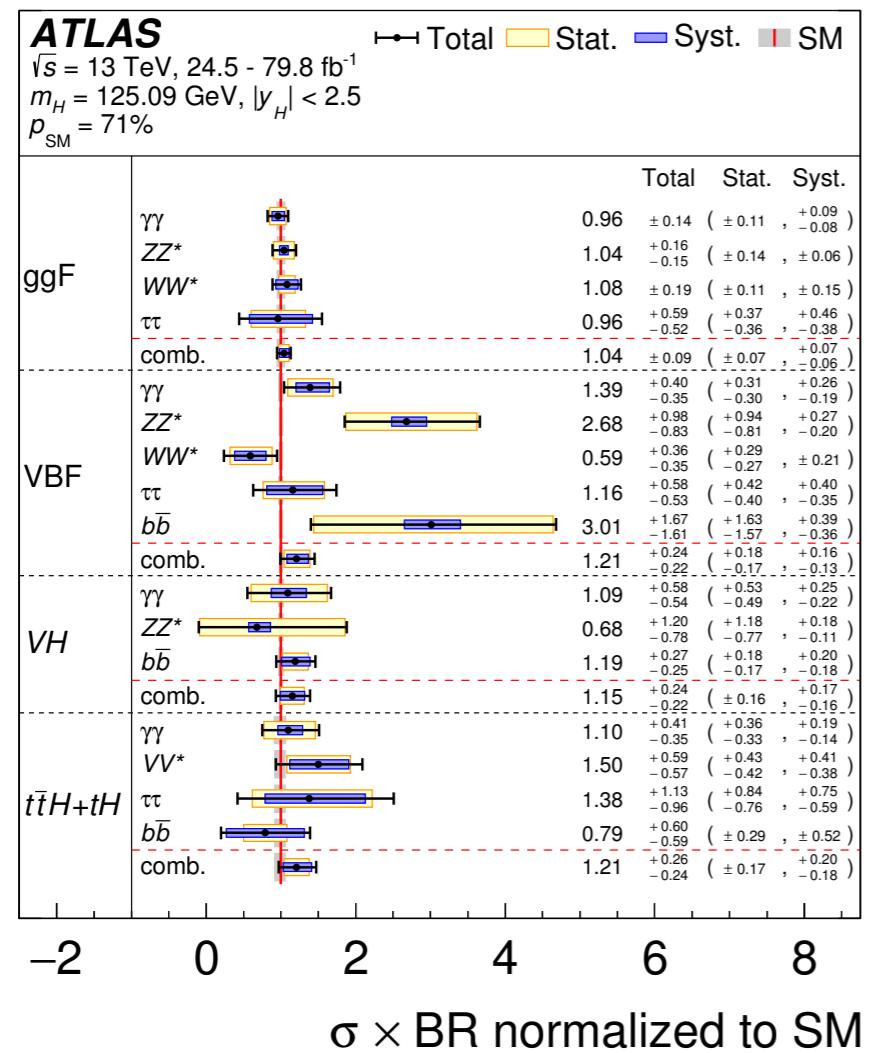

# Cross sections and branching fractions

Assuming a single, common  $\mu$ :

- Run 1 combination:  $\mu = 1.09 \pm 0.11$
- Run 2 ATLAS:  $\mu = 1.11 \pm 0.09$
- Run 2 CMS:  $\mu = 1.17 \pm 0.10$

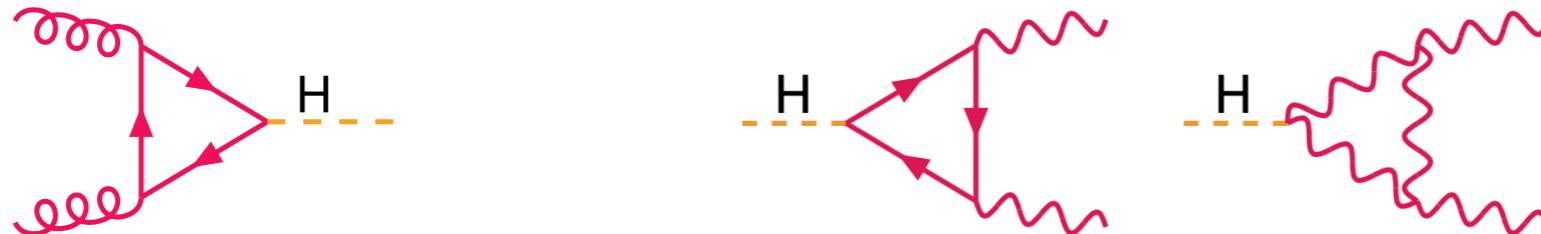

~ equal contributions from statistical, experimental, theoretical uncertainties

# Coupling constants (“ $\kappa$ framework”) (1)

Going beyond interpretation in “mere” terms of cross sections, branching fractions:

- obvious framework for interpretation: coupling constant modifiers
- fermions:  $y_f \rightarrow \kappa_f y_f$
- vector bosons:  $g_{W/Z} \rightarrow \kappa_{W/Z} g_{W/Z}$
- simplifying assumptions possible
- $gg \rightarrow H$  and  $H \rightarrow \gamma\gamma$ : loops so also sensitive to new physics contributions  
⇒ retain also  $\kappa_g, \kappa_\gamma$  interpretations

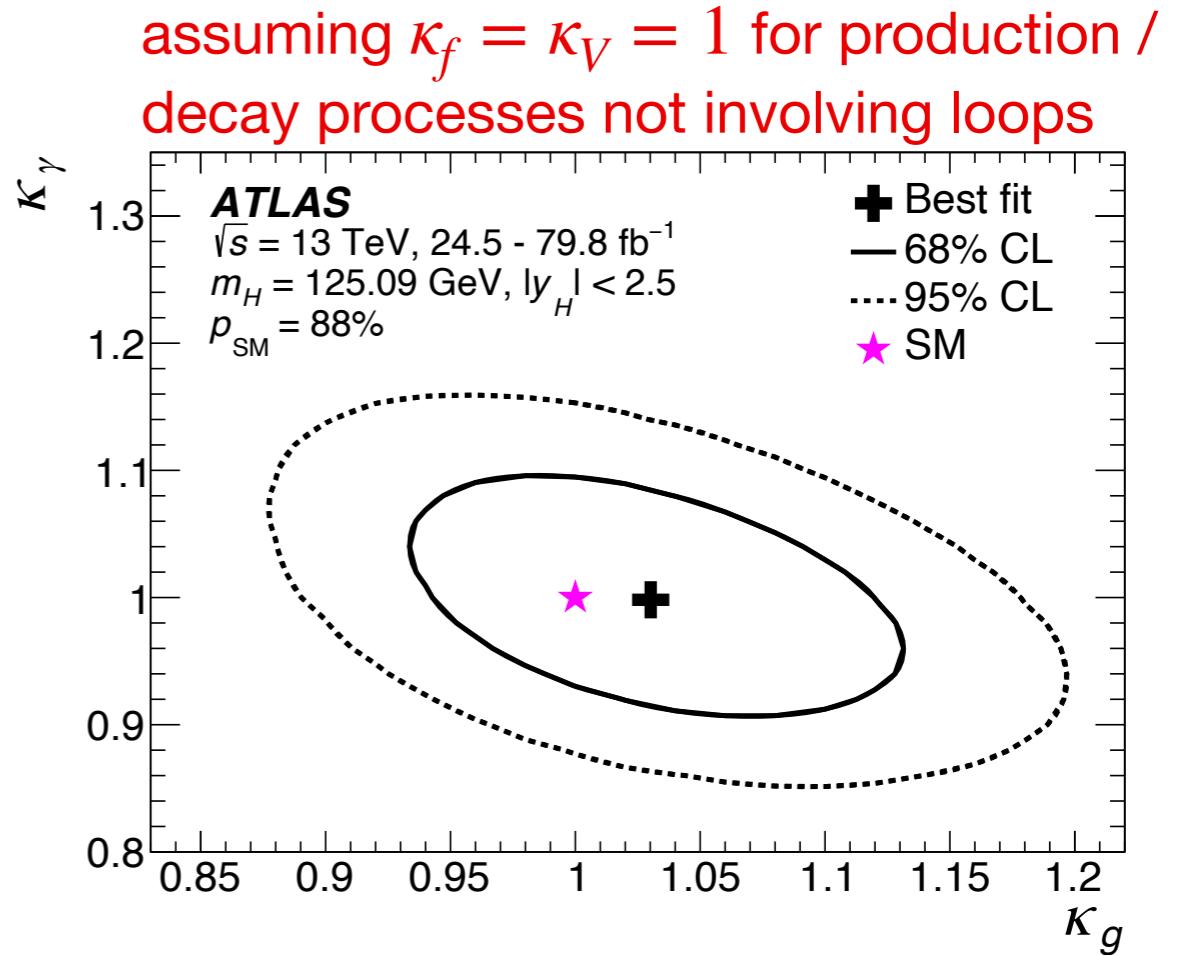

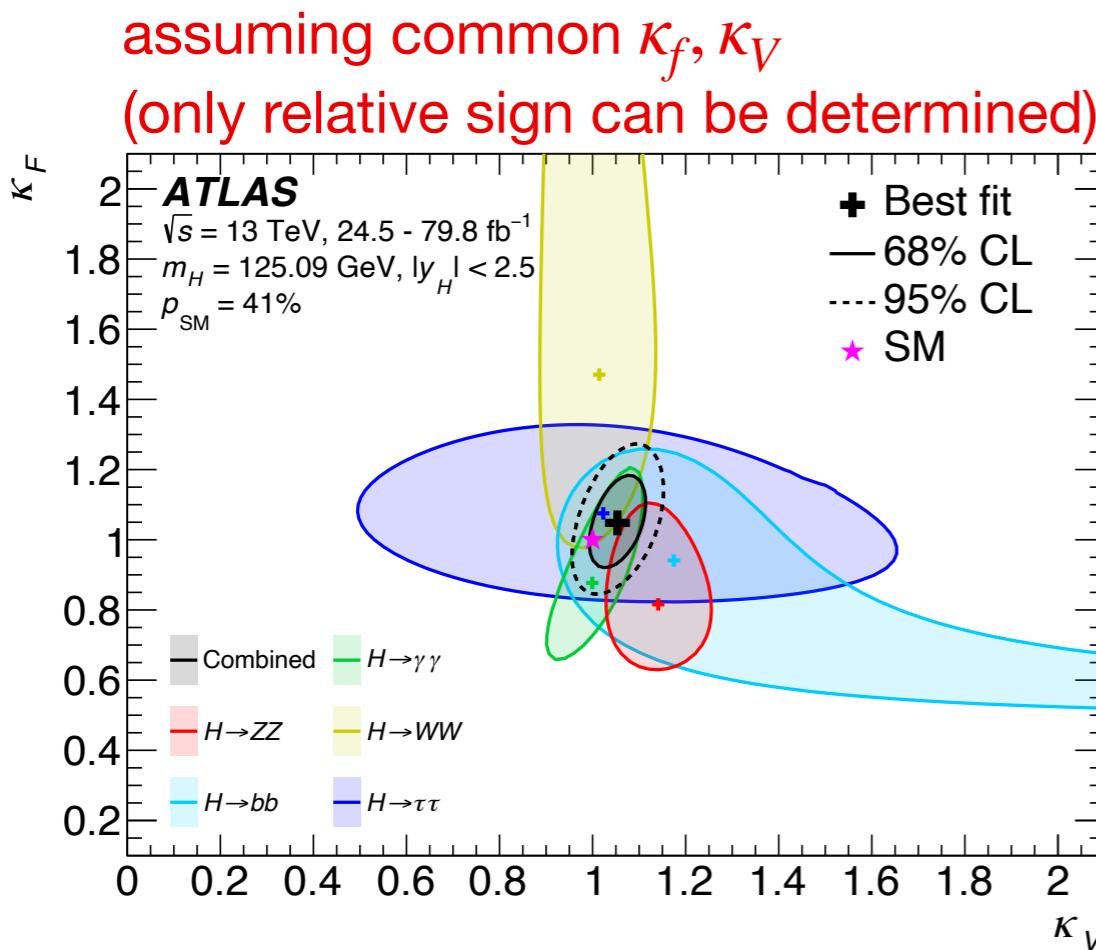

- “resolved” interpretation:  $\kappa_g^2 = 1.04\kappa_t^2 + 0.002\kappa_b^2 - 0.04\kappa_t\kappa_b$   
 $\kappa_\gamma^2 = 1.59\kappa_W^2 + 0.07\kappa_t^2 - 0.67\kappa_W\kappa_t$
- N.B.:  $\sigma(gg \rightarrow H)$  excludes 4<sup>th</sup> quark family with “usual” Yukawa couplings
- contributions become ~ mass independent for high mass

# Coupling constants (“ $\kappa$ framework”) (2)

Cross section for production process  $i$ , decay  $j$ :  $\sigma_i \text{Br}_j = \sigma_i \Gamma_j / \Gamma_H$ , with  $\Gamma_H = \sum_j \Gamma_j$   $\Rightarrow$  sensitivity not to just products of  $\kappa_i$

- $\Gamma_H$  could have contributions from non-standard decays
- weak constraints from limits on explicit  $H \rightarrow$  invisible searches in VBF,  $VH$  production ( $\text{Br}(H \rightarrow \text{invisible}) < \sim 0.2$ ); but mostly assumed to be 0

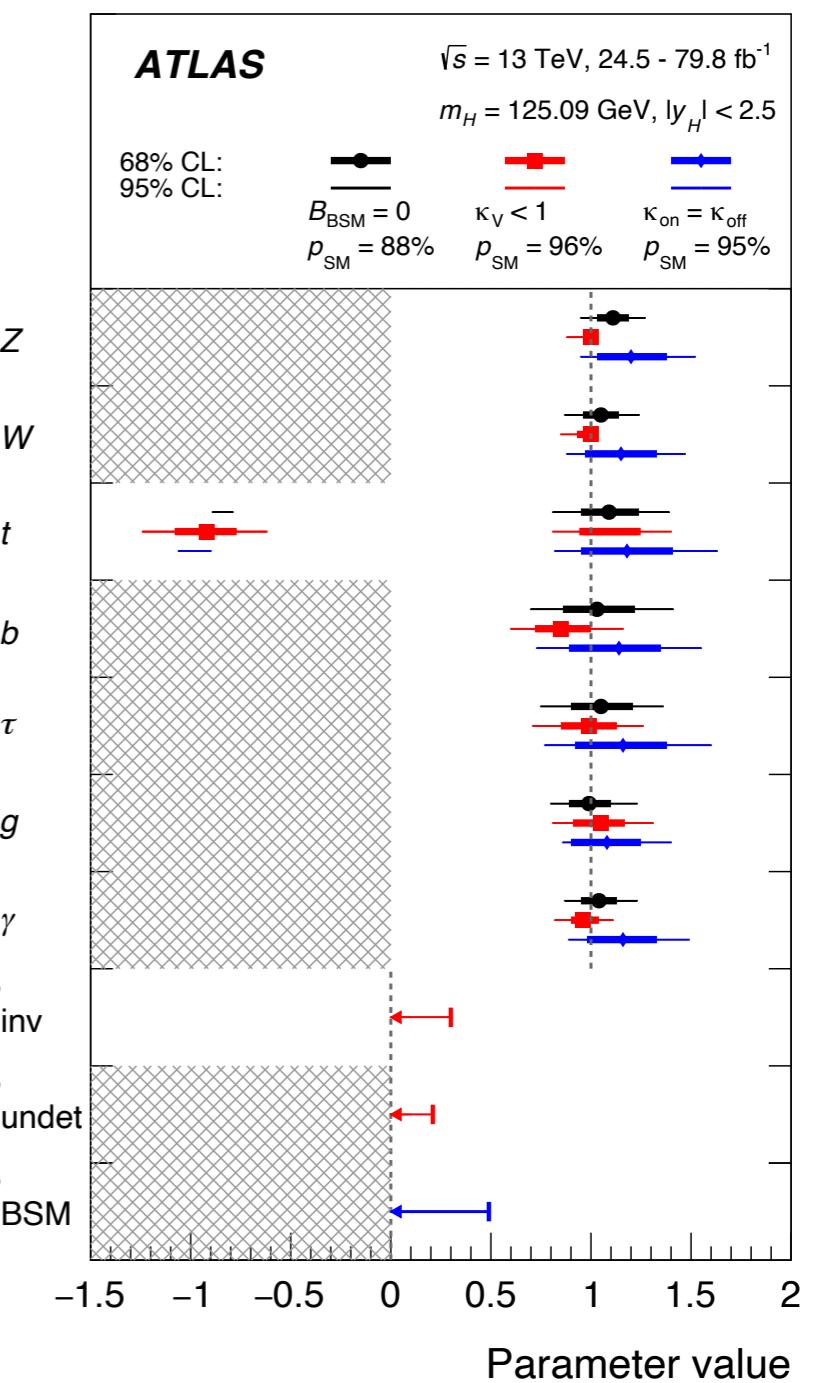

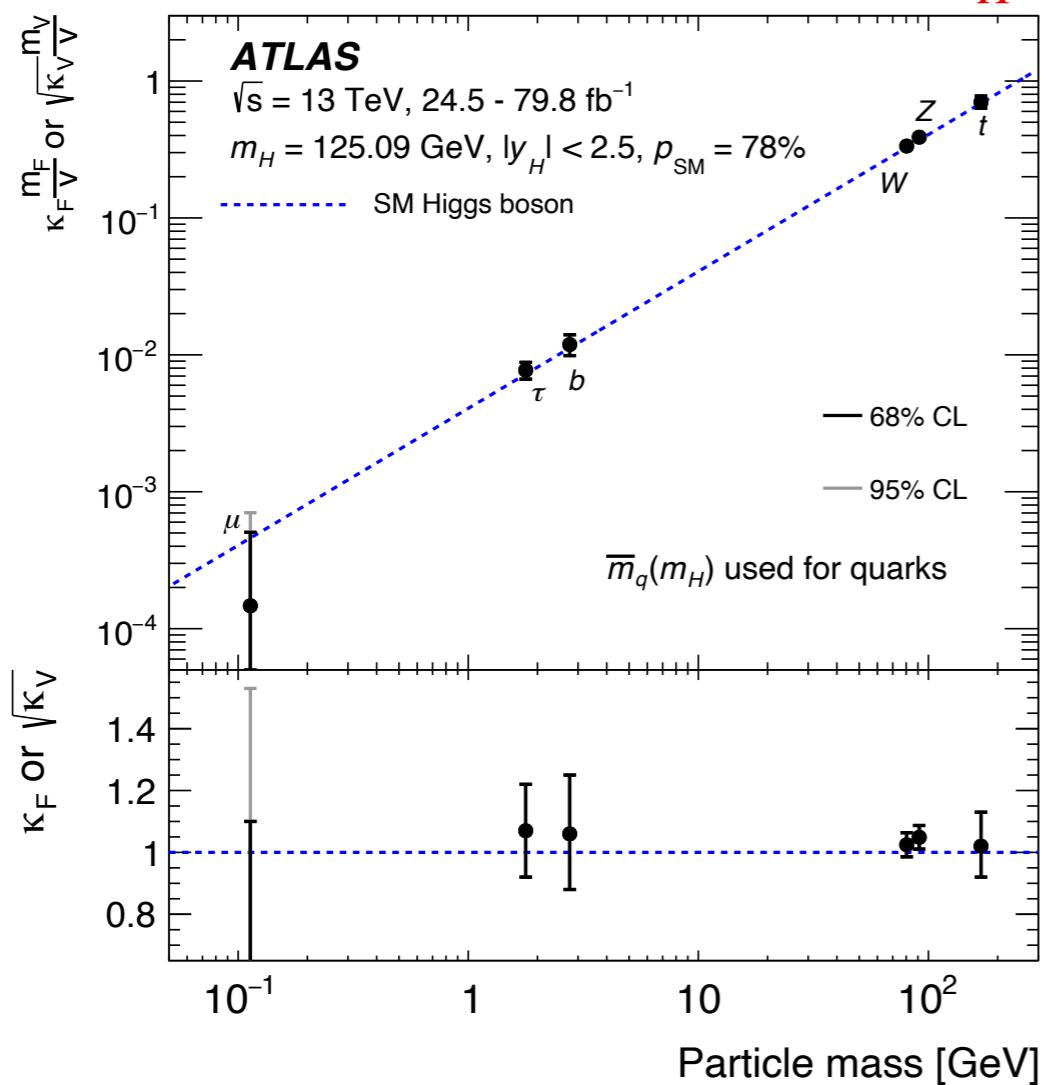

# Coupling constants (“ $\kappa$ framework”) (3)

Relaxing assumptions about relations between  $\kappa_i$

- using “resolved” expression for  $\kappa_g, \kappa_\gamma$  (left) or not (right)
- precision  $\sim 10\% (W/Z), \sim 15\% (t, b, \tau)$

not straight plots of  $y_f, \sqrt{g_{W/Z}}$  as  
couplings evaluated at scale  $m_H$

# Spin/parity determination (1)

Relax and test assumptions about Higgs spin and parity properties.

Sensitivity especially in decay angular distributions. For  $W, Z$ :

- spin 0:  $A(X \rightarrow VV) = v^{-1} \epsilon_1^{*\mu} \epsilon_2^{*\nu} \left( \underline{a_1 g_{\mu\nu} m_X^2} + \underline{a_2 q_\mu q_\nu} + a_3 \epsilon_{\mu\nu\alpha\beta} q_1^\alpha q_2^\beta \right)$  0+, 0-
- spin 2:

$$\begin{aligned}
 A(X \rightarrow VV) = & \Lambda^{-1} \left[ \underline{2g_1^{(2)} t_{\mu\nu} f^{*1,\mu\alpha} f^{*2,\nu\alpha}} + 2g_2^{(2)} t_{\mu\nu} \frac{q_\alpha q_\beta}{\Lambda^2} f^{*1,\mu\alpha} f^{*2,\nu\beta} \right. \\
 & + g_3^{(2)} \frac{\tilde{q}^\beta \tilde{q}^\alpha}{\Lambda^2} t_{\beta\nu} (f^{*1,\mu\nu} f^{*2}_{\mu\alpha} + f^{*2,\mu\nu} f^{*1}_{\mu\alpha}) + g_4^{(2)} \frac{\tilde{q}^\nu \tilde{q}^\mu}{\Lambda^2} t_{\mu\nu} f^{*1,\alpha\beta} f^{*(2)}_{\alpha\beta} \\
 & + m_V^2 \left( \underline{2g_5^{(2)} t_{\mu\nu} \epsilon_1^{*\mu} \epsilon_2^{*\nu}} + 2g_6^{(2)} \frac{\tilde{q}^\mu q_\alpha}{\Lambda^2} t_{\mu\nu} (\epsilon_1^{*\nu} \epsilon_2^{*\alpha} - \epsilon_1^{*\alpha} \epsilon_2^{*\nu}) + g_7^{(2)} \frac{\tilde{q}^\mu \tilde{q}^\nu}{\Lambda^2} t_{\mu\nu} \epsilon_1^* \epsilon_2^* \right) \\
 & \left. + g_8^{(2)} \frac{\tilde{q}_\mu \tilde{q}_\nu}{\Lambda^2} t_{\mu\nu} f^{*1,\alpha\beta} \tilde{f}^{*(2)}_{\alpha\beta} + g_9^{(2)} t_{\mu\alpha} \tilde{q}^\alpha \epsilon_{\mu\nu\rho\sigma} \epsilon_1^{*\nu} \epsilon_2^{*\rho} q^\sigma + \frac{g_{10}^{(2)} t_{\mu\alpha} \tilde{q}^\alpha}{\Lambda^2} \epsilon_{\mu\nu\rho\sigma} q^\rho \tilde{q}^\sigma (\epsilon_1^{*\nu} (q \epsilon_2^*) + \epsilon_2^{*\nu} (q \epsilon_1^*)) \right]
 \end{aligned}$$

graviton-like tensor:  
 $g_1^{(2)}=g_5^{(2)}$

- only polarisation states  $\pm 1$  ( $q\bar{q}$ ),  $\pm 2$  ( $gg$ ) possible  $\Rightarrow$  predictions depend on fraction of events produced from each initial state
- spin 1 also considered but excluded by Landau-Yang theorem ( $H \rightarrow \gamma\gamma$ )

# Spin/parity determination (1)

Relax and test assumptions about Higgs spin and parity properties.

Sensitivity especially in decay angular distributions. For  $W, Z$ :

- spin 0:  $A(X \rightarrow VV) = v^{-1} \epsilon_1^{*\mu} \epsilon_2^{*\nu} \left( \underline{a_1 g_{\mu\nu} m_X^2} + \underline{a_2 q_\mu q_\nu} + a_3 \epsilon_{\mu\nu\alpha\beta} q_1^\alpha q_2^\beta \right)$  0+, 0-
- spin 2:

$$\begin{aligned}
 A(X \rightarrow VV) = & \Lambda^{-1} \left[ \underline{2g_1^{(2)} t_{\mu\nu} f^{*1,\mu\alpha} f^{*2,\nu\alpha}} + 2g_2^{(2)} t_{\mu\nu} \frac{q_\alpha q_\beta}{\Lambda^2} f^{*1,\mu\alpha} f^{*2,\nu\beta} \right. \\
 & + g_3^{(2)} \frac{\tilde{q}^\beta \tilde{q}^\alpha}{\Lambda^2} t_{\beta\nu} (f^{*1,\mu\nu} f^{*2}_{\mu\alpha} + f^{*2,\mu\nu} f^{*1}_{\mu\alpha}) + g_4^{(2)} \frac{\tilde{q}^\nu \tilde{q}^\mu}{\Lambda^2} t_{\mu\nu} f^{*1,\alpha\beta} f^{*(2)}_{\alpha\beta} \\
 & + m_V^2 \left( \underline{2g_5^{(2)} t_{\mu\nu} \epsilon_1^{*\mu} \epsilon_2^{*\nu}} + 2g_6^{(2)} \frac{\tilde{q}^\mu q_\alpha}{\Lambda^2} t_{\mu\nu} (\epsilon_1^{*\nu} \epsilon_2^{*\alpha} - \epsilon_1^{*\alpha} \epsilon_2^{*\nu}) + g_7^{(2)} \frac{\tilde{q}^\mu \tilde{q}^\nu}{\Lambda^2} t_{\mu\nu} \epsilon_1^* \epsilon_2^* \right) \\
 & \left. + g_8^{(2)} \frac{\tilde{q}_\mu \tilde{q}_\nu}{\Lambda^2} t_{\mu\nu} f^{*1,\alpha\beta} \tilde{f}^{*(2)}_{\alpha\beta} + g_9^{(2)} t_{\mu\alpha} \tilde{q}^\alpha \epsilon_{\mu\nu\rho\sigma} \epsilon_1^{*\nu} \epsilon_2^{*\rho} q^\sigma + \frac{g_{10}^{(2)} t_{\mu\alpha} \tilde{q}^\alpha}{\Lambda^2} \epsilon_{\mu\nu\rho\sigma} q^\rho \tilde{q}^\sigma (\epsilon_1^{*\nu} (q \epsilon_2^*) + \epsilon_2^{*\nu} (q \epsilon_1^*)) \right]
 \end{aligned}$$

graviton-like tensor:  
 $g_1^{(2)}=g_5^{(2)}$

- only polarisation states  $\pm 1$  ( $q\bar{q}$ ),  $\pm 2$  ( $gg$ ) possible  $\Rightarrow$  predictions depend on fraction of events produced from each initial state
- spin 1 also considered but excluded by Landau-Yang theorem ( $H \rightarrow \gamma\gamma$ )

Not an exhaustive list of options!

- CP admixtures in principle possible (property of the coupling, not the particle)

# Spin/parity determination (2)

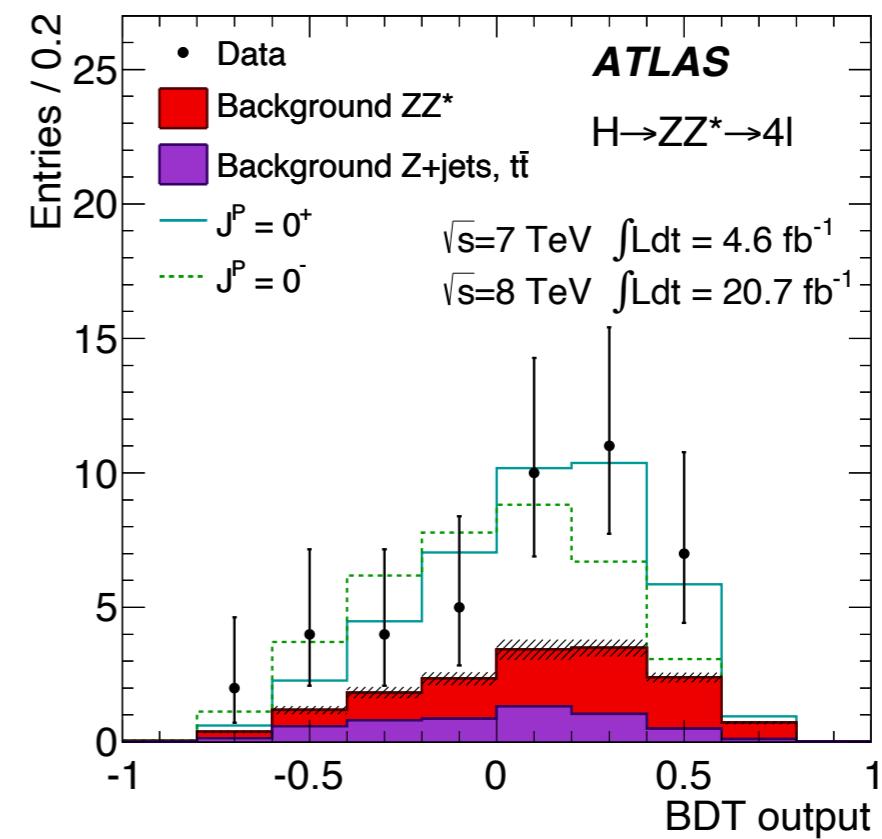

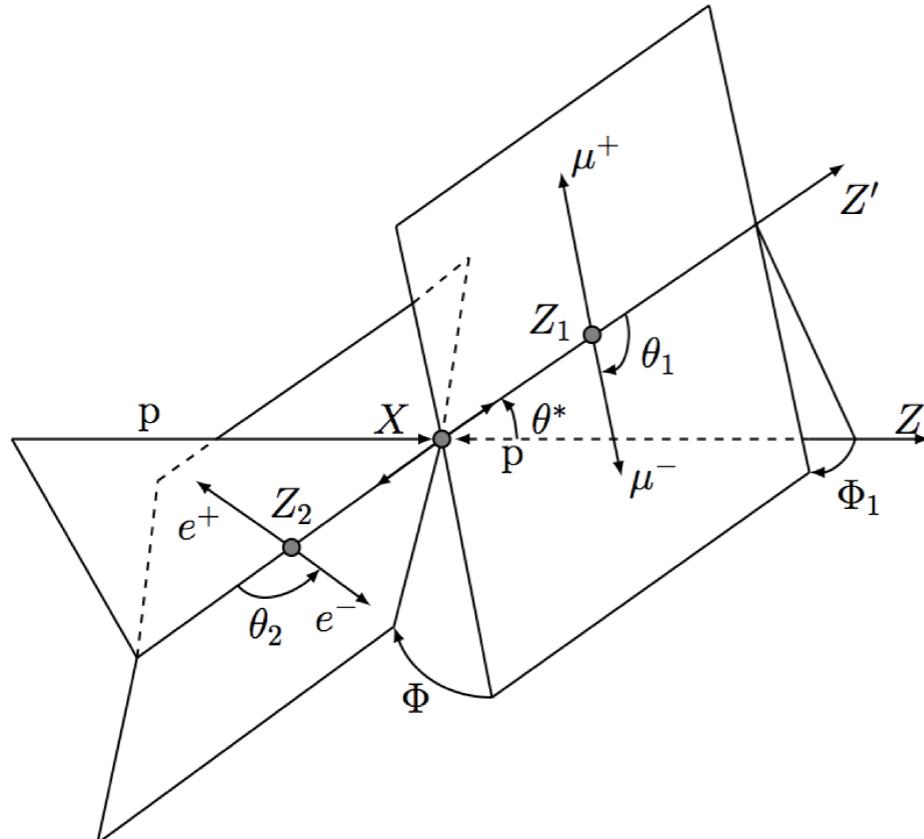

Maximum information can be obtained from  $H \rightarrow WW$ ,  $ZZ$  analyses  
(leptons carry information about  $W$ ,  $Z$  spins)

- some information also from angular distribution in  $H \rightarrow \gamma\gamma$  & from VBF production (studied in  $H \rightarrow \tau^+\tau^-$ )

Example:  $H \rightarrow ZZ^*$ : 5 angles in addition to  $m_{12}, m_{34}$

- build BDTs using all information, trained to distinguish each spin/parity hypothesis from the  $0^+$  one

Other pure  $J^P$  hypotheses than the Standard Model's  $J^P = 0^+$  ruled out

# Spin/parity determination (3)

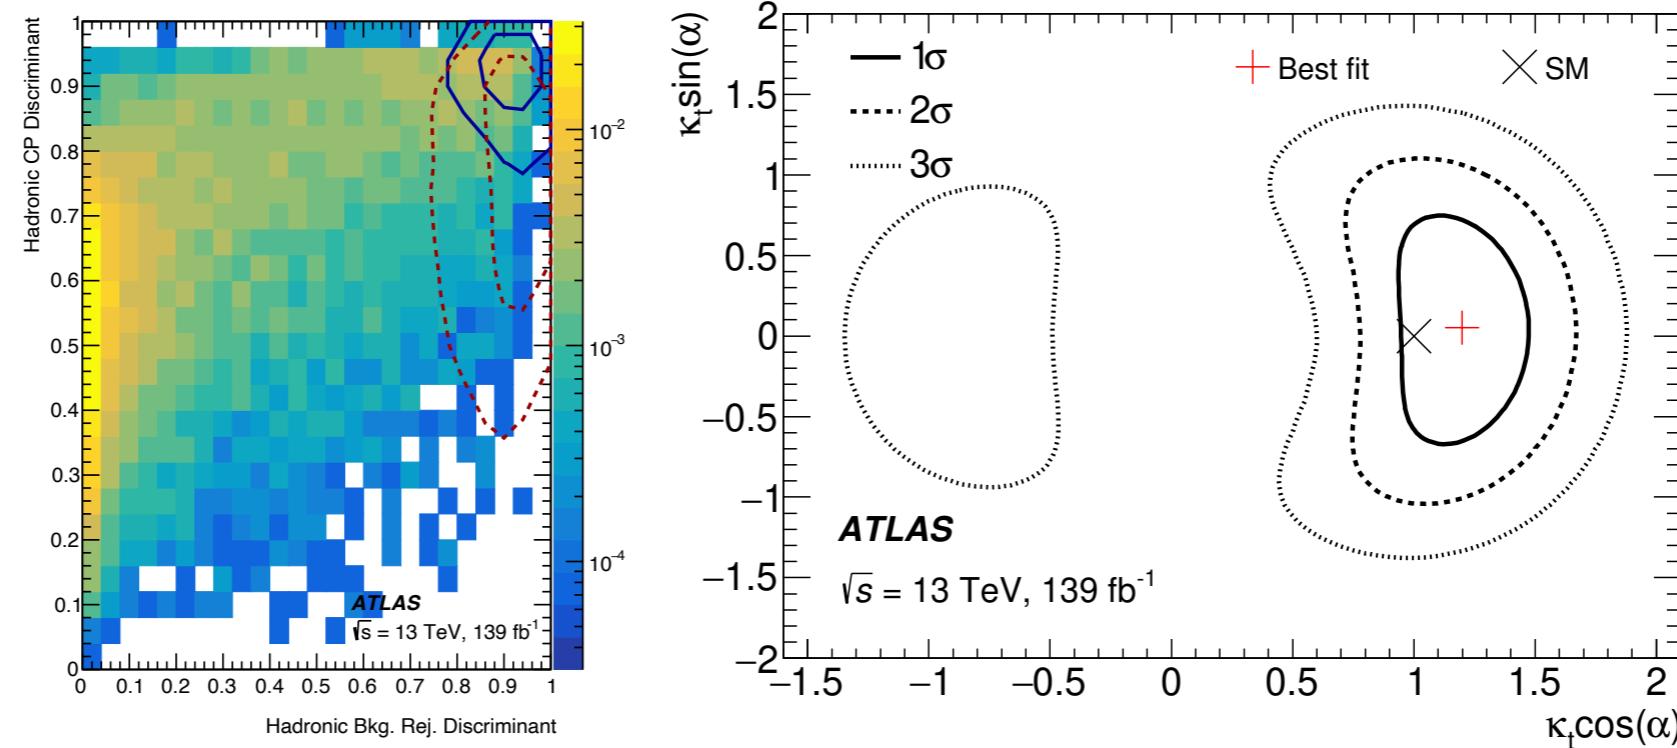

As parity is a property of the coupling, it must be investigated separately for couplings to fermions. General formulation:

$$\mathcal{L}_{ffH} = -\kappa_f y_{f,\text{SM}} \bar{f}(\cos \alpha + i \sin \alpha \gamma^5) f h$$

Studied:  $t\bar{t}H$

- $t, \bar{t}$  polarisation analysed using decay products' angular information
- $H \rightarrow \gamma\gamma$  cleanest as little confusion with other objects in final state
  - still a complex analysis with highest sensitivity using multivariate analysis

Combined ATLAS & CMS results exclude pure CP-odd hypothesis with  $\sim 5\sigma$

# Total decay width (1)

Using on-shell Higgs boson production only, it is not possible to obtain independent information on  $\Gamma_H$   $\Rightarrow$  use also off-shell production

- off-shell:  $\sigma \propto \kappa_i^2 \kappa_f^2$
  - on-shell:  $\sigma \propto \frac{\kappa_i^2 \kappa_f^2}{(s - m_H)^2 + m_H^2 \Gamma_H^2} \xrightarrow{\text{NWA}} \frac{\pi}{m_H \Gamma_H} \delta(s - m_H^2) \kappa_i^2 \kappa_f^2$
- $\Rightarrow$  ratio sensitive to  $\Gamma_H$
- } assumes that on- and off-shell  $\kappa$  are identical

Studied notably in  $gg \rightarrow H \rightarrow ZZ^{(*)}$

- off-shell complications:

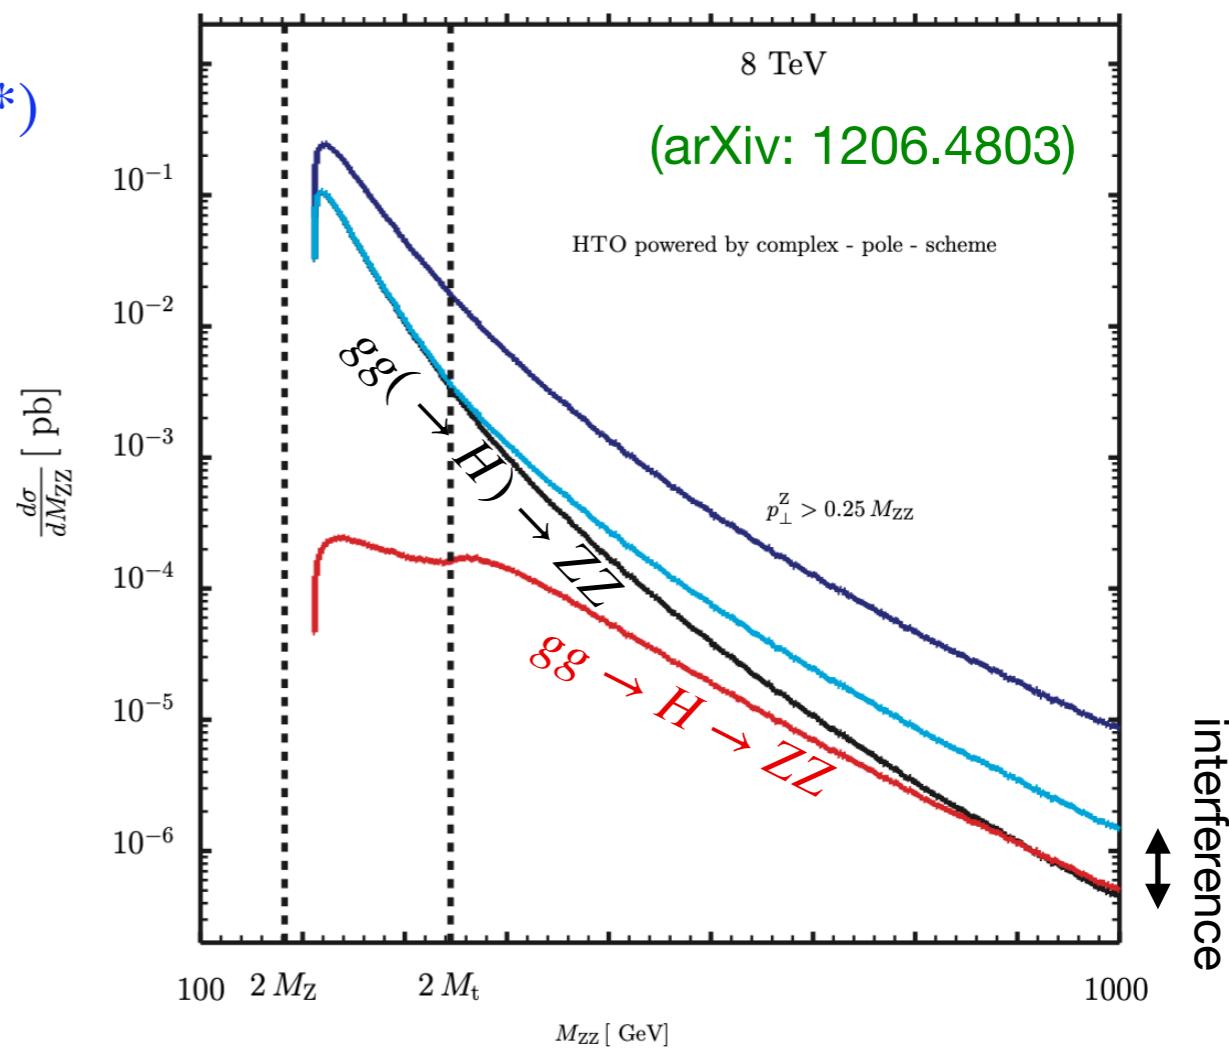

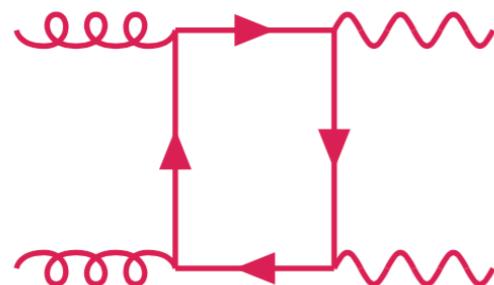

# Total decay width (1)

Using on-shell Higgs boson production only, it is not possible to obtain independent information on  $\Gamma_H \rightarrow \text{use also off-shell production}$

- off-shell:  $\sigma \propto \kappa_i^2 \kappa_f^2$
  - on-shell:  $\sigma \propto \frac{\kappa_i^2 \kappa_f^2}{(s - m_H)^2 + m_H^2 \Gamma_H^2} \xrightarrow{\text{NWA}} \frac{\pi}{m_H \Gamma_H} \delta(s - m_H^2) \kappa_i^2 \kappa_f^2$
- ⇒ ratio sensitive to  $\Gamma_H$

Studied notably in  $gg \rightarrow H \rightarrow ZZ^{(*)}$

- off-shell complications:
  - sizeable contribution from continuum  $gg \rightarrow ZZ$
  - interference > pure  $H$  contribution

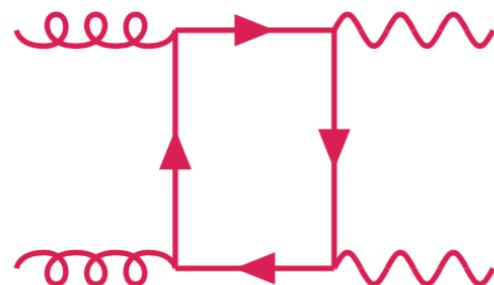

# Total decay width (1)

Using on-shell Higgs boson production only, it is not possible to obtain independent information on  $\Gamma_H \rightarrow ZZ$   $\rightarrow$  use also off-shell production

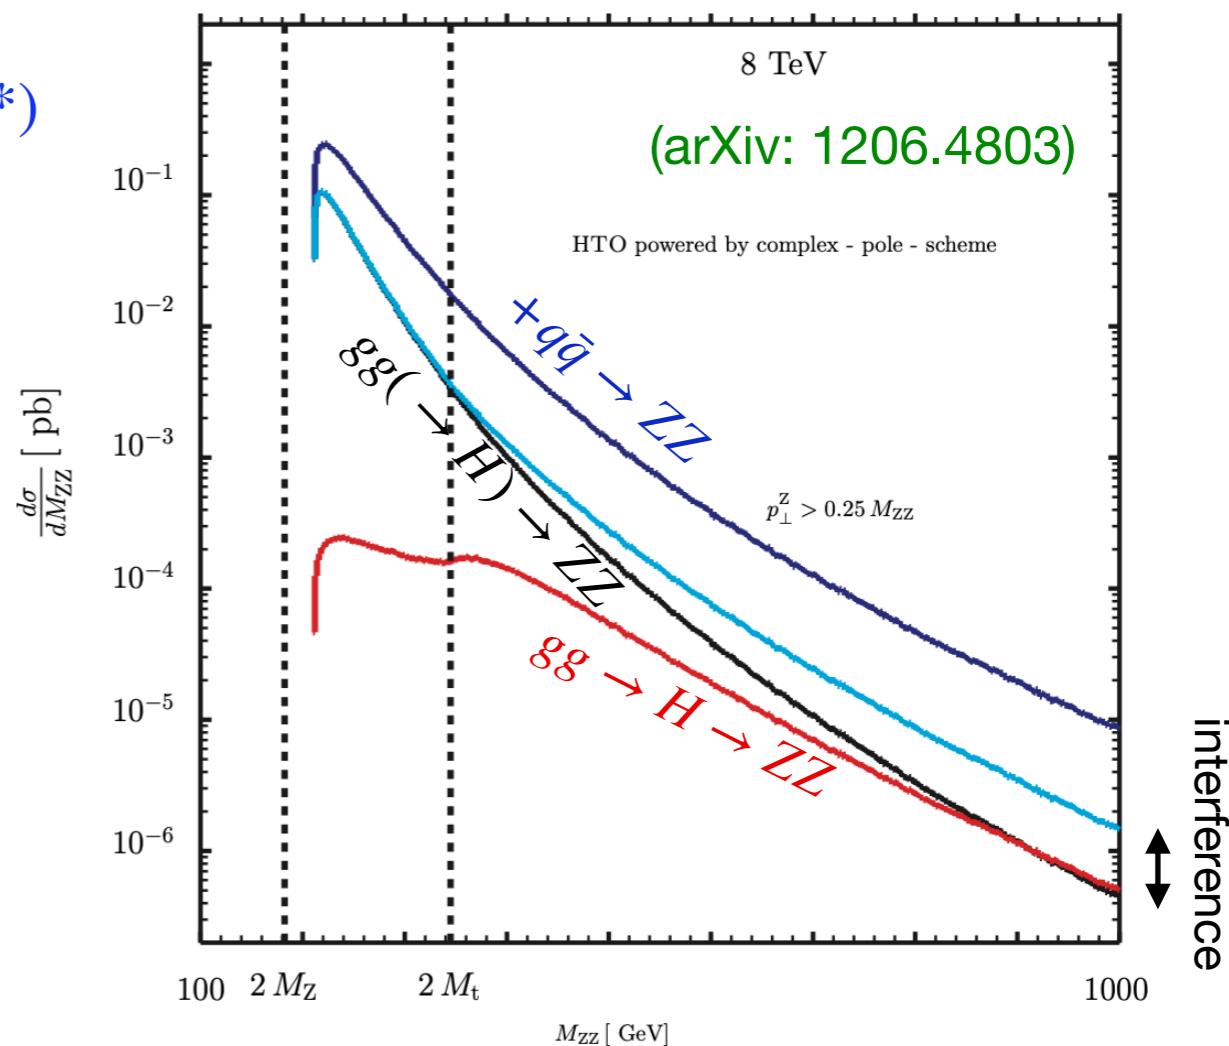

- off-shell:  $\sigma \propto \kappa_i^2 \kappa_f^2$
  - on-shell:  $\sigma \propto \frac{\kappa_i^2 \kappa_f^2}{(s - m_H)^2 + m_H^2 \Gamma_H^2} \xrightarrow{\text{NWA}} \frac{\pi}{m_H \Gamma_H} \delta(s - m_H^2) \kappa_i^2 \kappa_f^2$
- $\rightarrow$  ratio sensitive to  $\Gamma_H$

Studied notably in  $gg \rightarrow H \rightarrow ZZ^{(*)}$

- off-shell complications:
  - sizeable contribution from continuum  $gg \rightarrow ZZ$
  - interference > pure  $H$  contribution

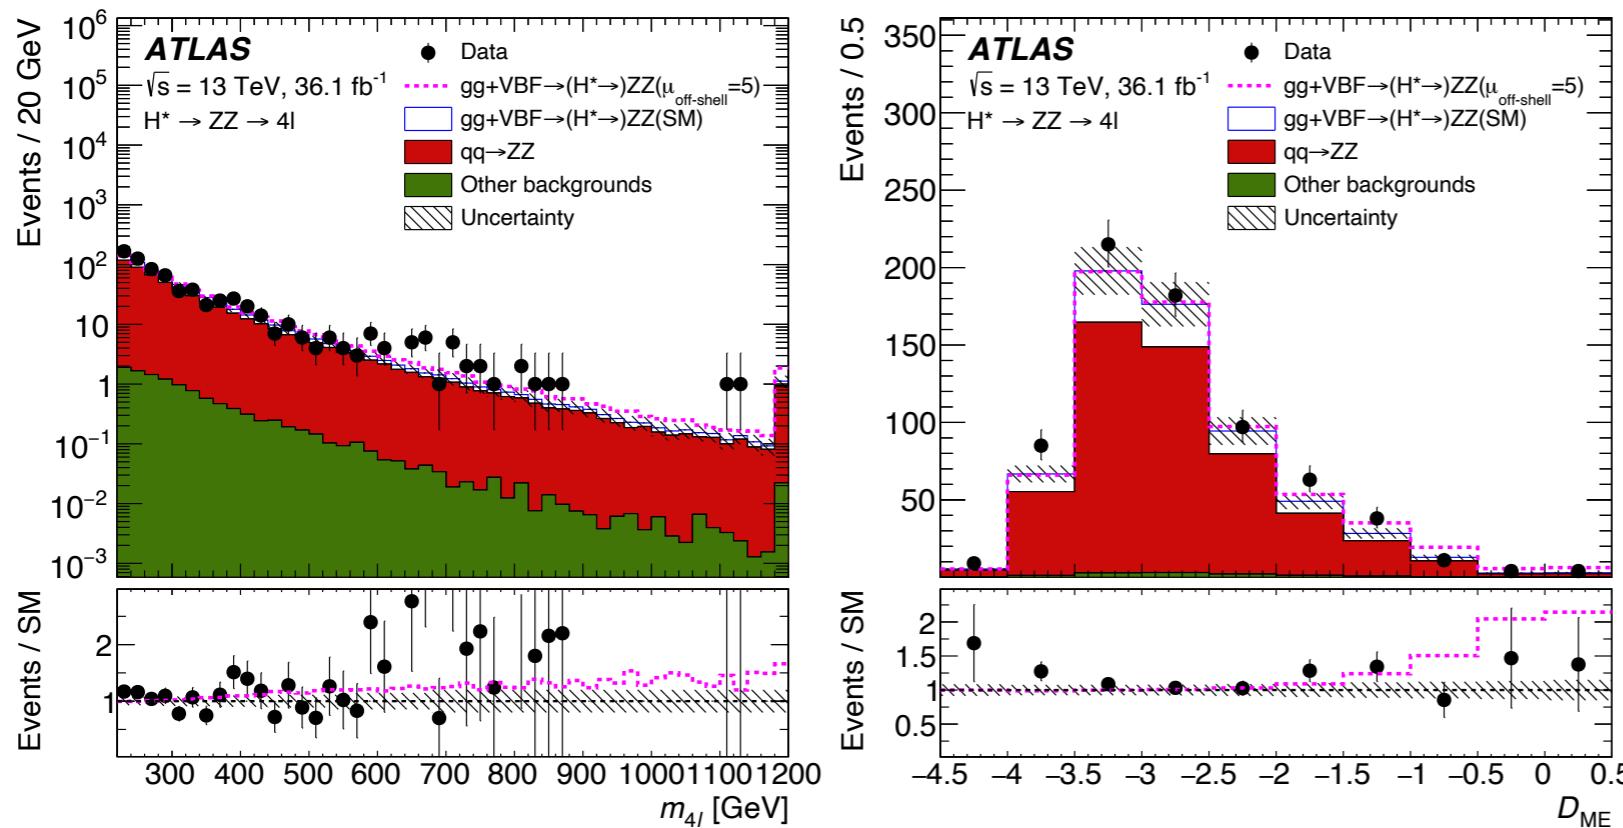

- $q\bar{q} \rightarrow ZZ$  bkg

# Total decay width (2)

ATLAS Analysis is designed to distinguish signal  $gg \rightarrow H \rightarrow ZZ$  from continuum  $gg \rightarrow ZZ$  &  $q\bar{q} \rightarrow ZZ$

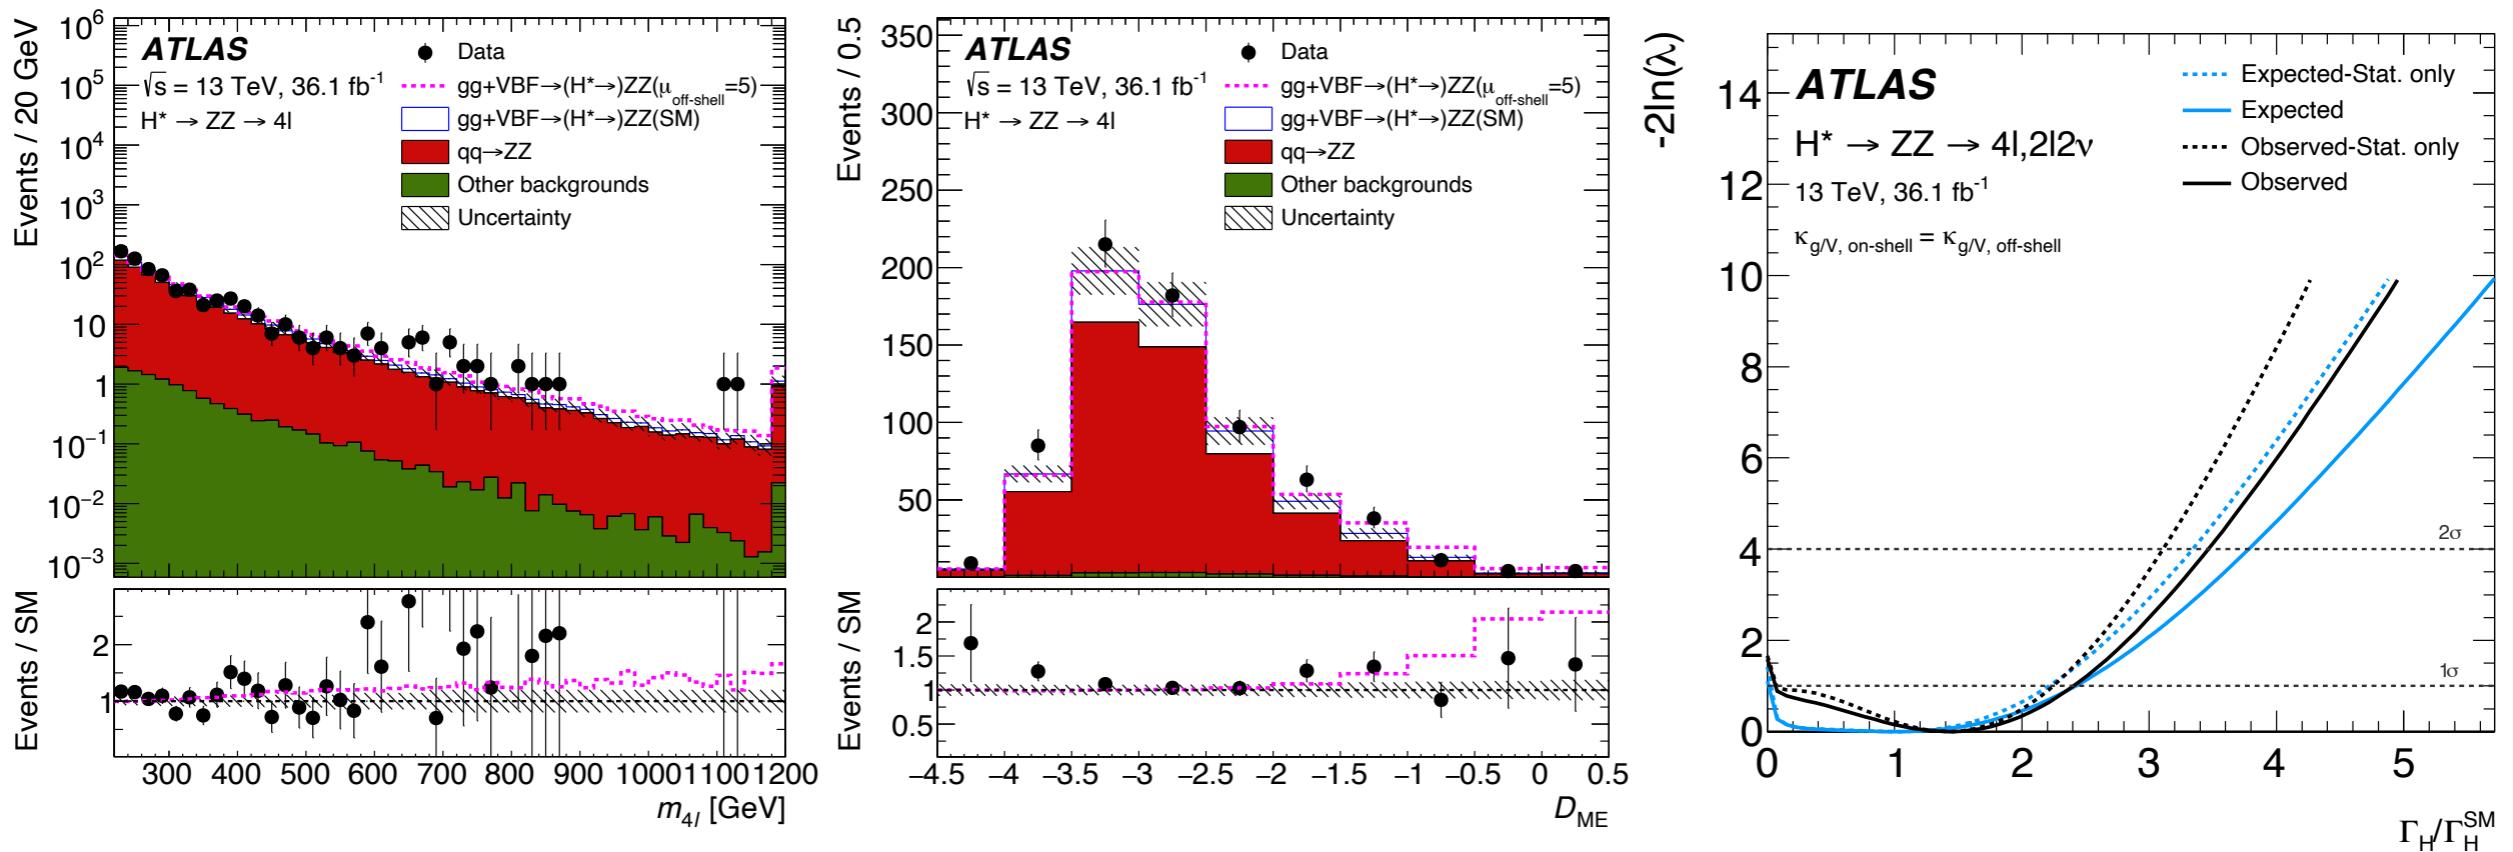

- discriminating power despite  $gg \rightarrow ZZ$  forming irreducible background

# Total decay width (2)

ATLAS Analysis is designed to distinguish signal  $gg \rightarrow H \rightarrow ZZ$  from continuum  $gg \rightarrow ZZ$  &  $q\bar{q} \rightarrow ZZ$

- discriminating power despite  $gg \rightarrow ZZ$  forming irreducible background

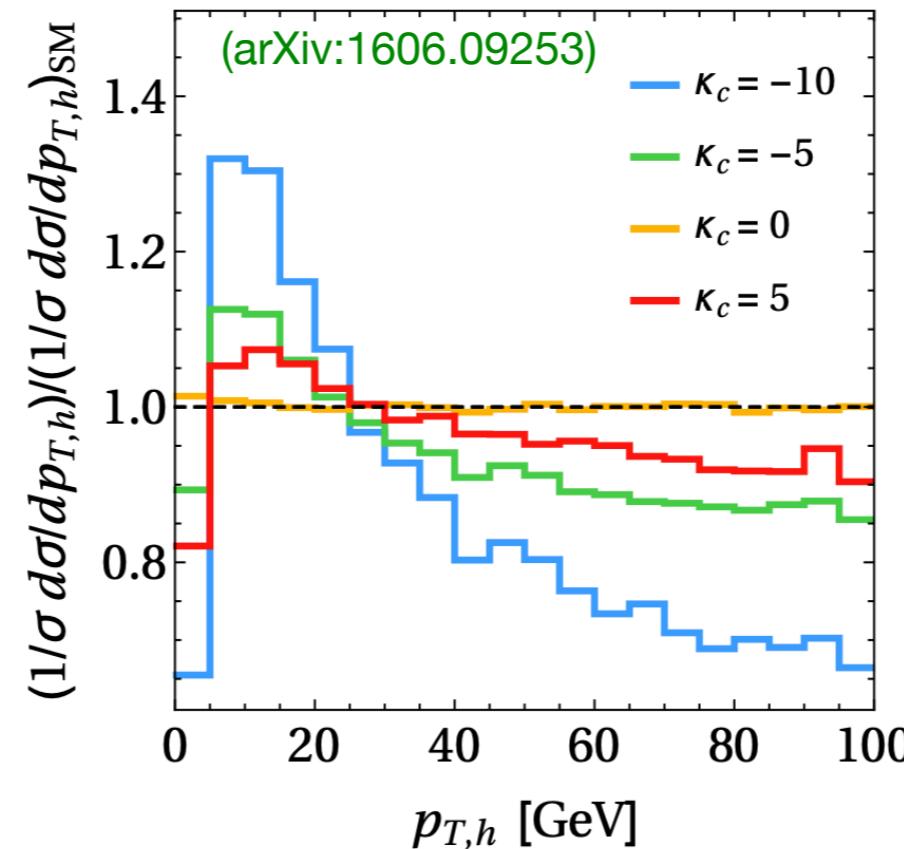

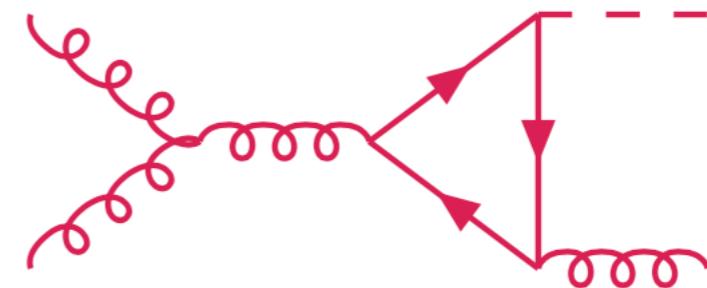

$\Gamma_H < 14.2 \text{ MeV}$  at 95% CL

- result also includes  $H \rightarrow ZZ \rightarrow \ell^+\ell^-\nu\bar{\nu}$ ,  $H \rightarrow W^+W^- \rightarrow \ell^+\nu_\ell\ell'^-\bar{\nu}_{\ell'}$
- CMS analysis is significantly more precise ( $\Gamma_H = 3.2^{+2.8}_{-2.2} \text{ MeV}$ ) but makes more specific assumptions as well

# Differential cross section measurements (1)

Access to properties beyond those discussed before, e.g.

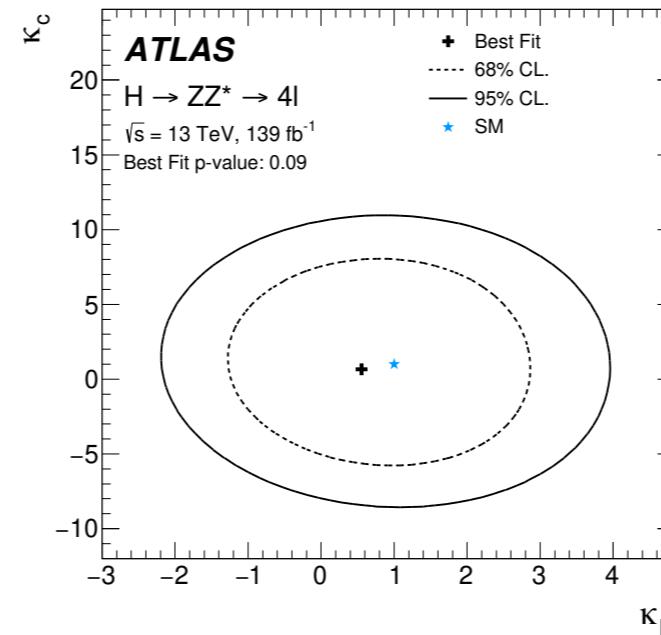

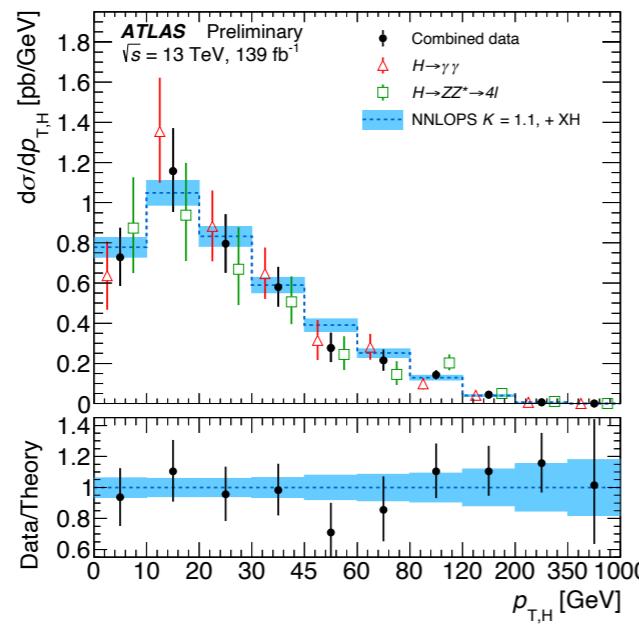

- $y_H$  (in  $gg \rightarrow H$ ): sensitive in particular to  $g(x)$
- $p_{T,H}$  (in  $H+\text{jets}$ ): non-negligible contribution from  $b, c$  quarks
  - at LO:  $\kappa_i \frac{m_i^2}{m_H^2} \ln^2(p_T^2/m_i^2)$
  - access to  $Hcc$  coupling
  - as an alternative to direct search for  $H \rightarrow c\bar{c}$  (e.g. in  $VH$  production)

# Differential cross section measurements (2)

“Cleanest” measurements possible in  $H \rightarrow 4\ell, H \rightarrow \gamma\gamma$

- unfold in order to compare with detailed theoretical predictions

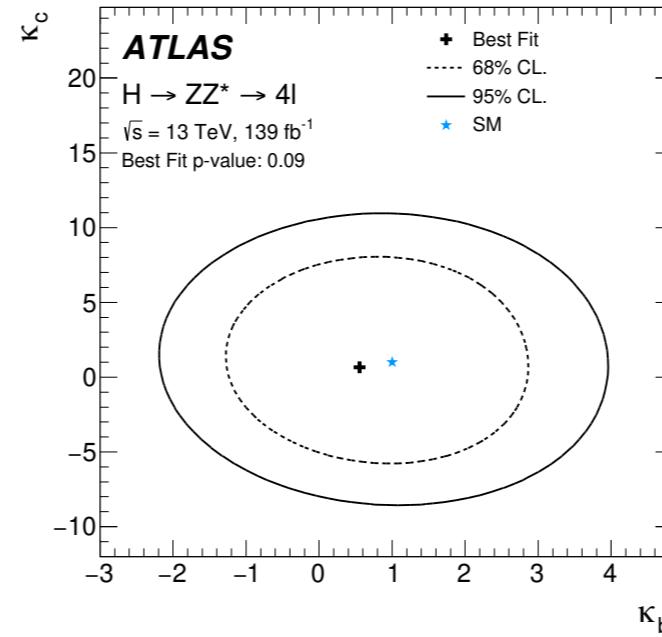

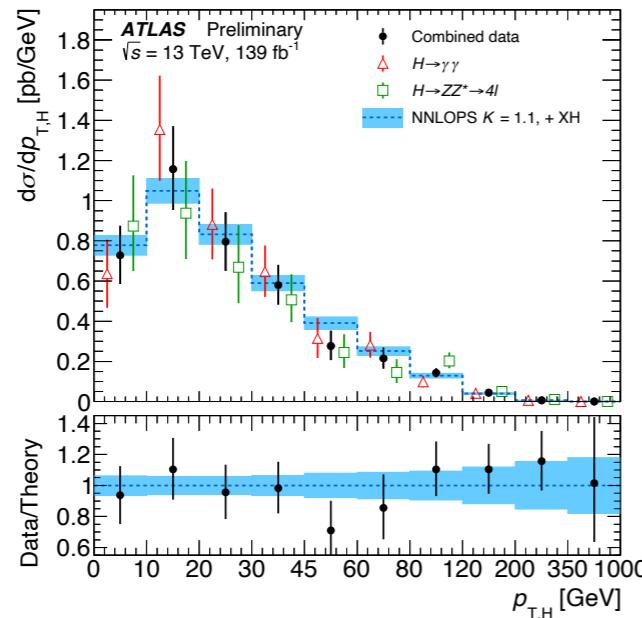

assuming SM cross  
section modified by  
 $\kappa_b, \kappa_c$  only

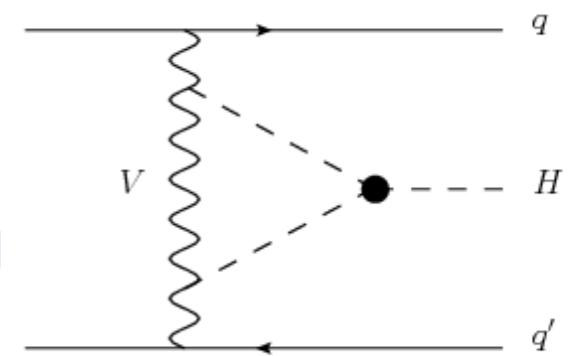

# Differential cross section measurements (2)

“Cleanest” measurements possible in  $H \rightarrow 4\ell, H \rightarrow \gamma\gamma$

- unfold in order to compare with detailed theoretical predictions

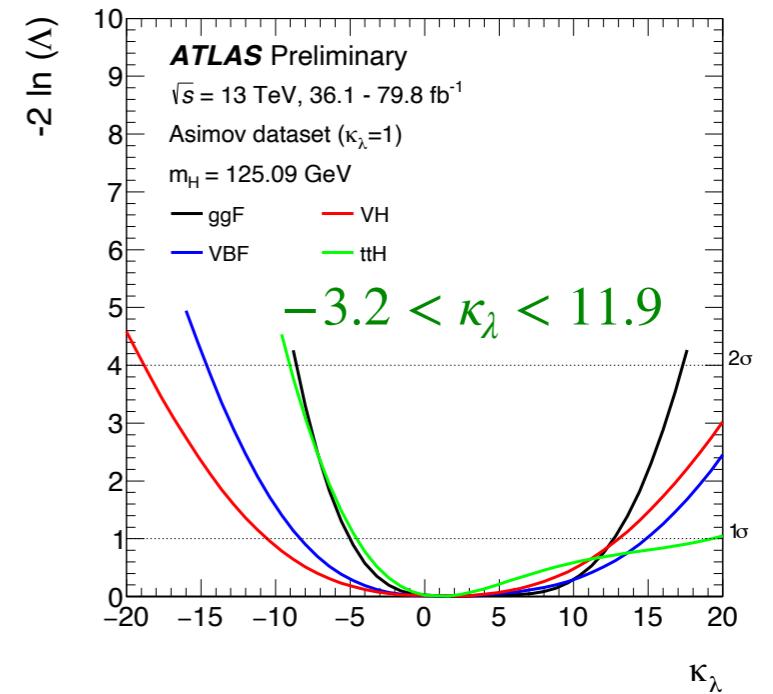

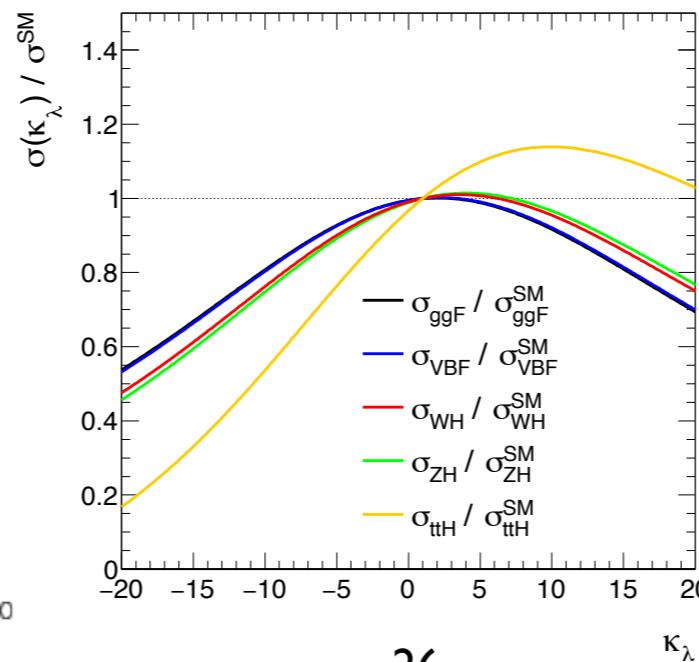

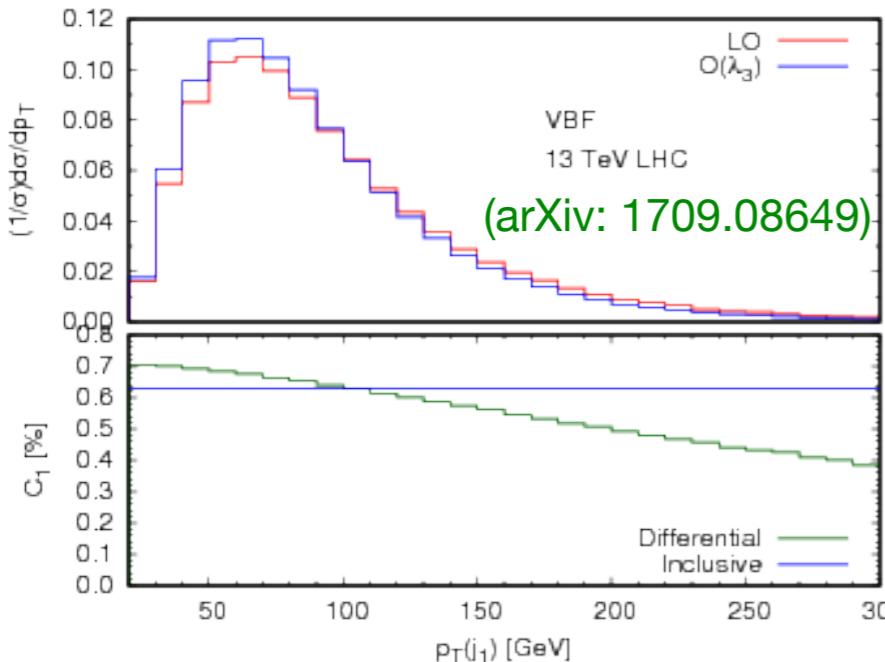

assuming SM cross section modified by  $\kappa_b, \kappa_c$  only

Alternative interpretation: Higgs-boson self-coupling

- also affects overall rates & branching fractions

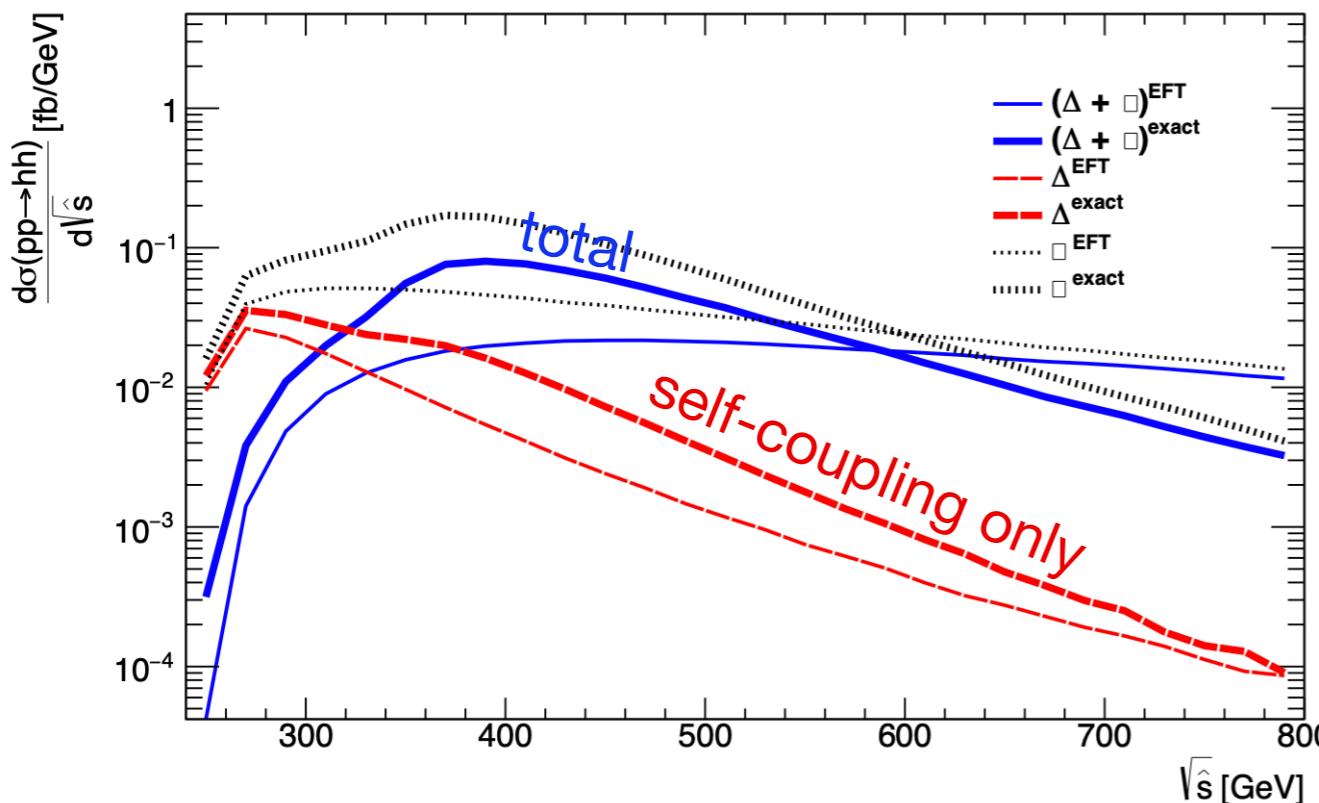

# Searches

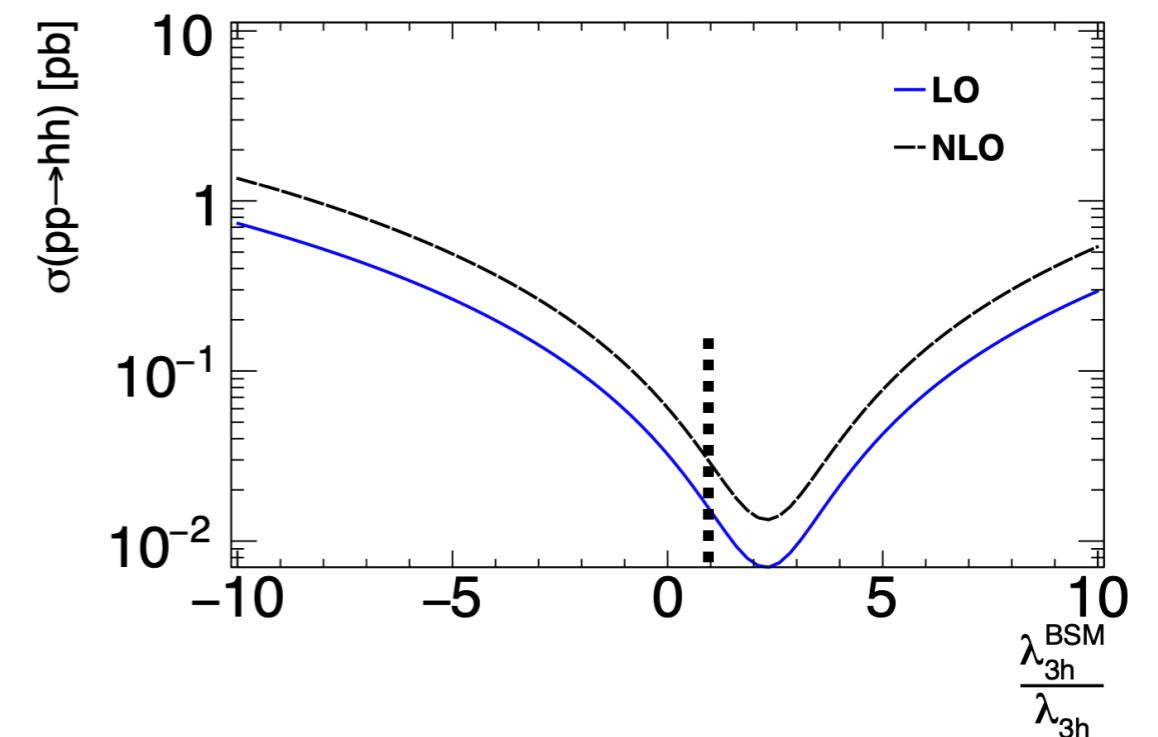

# Higgs boson pair production (1)

$HH$  production is a much more direct way to probe the Higgs boson's self-coupling

- cross section dominated by  $H^* \rightarrow HH$
- as opposed to  $H \rightarrow H^*H^*$
- large (destructive) interference effects between self-coupling, box diagrams
- significant dependence on  $\kappa_\lambda$

(plots from PhD thesis Wouter van den Wollenberg)

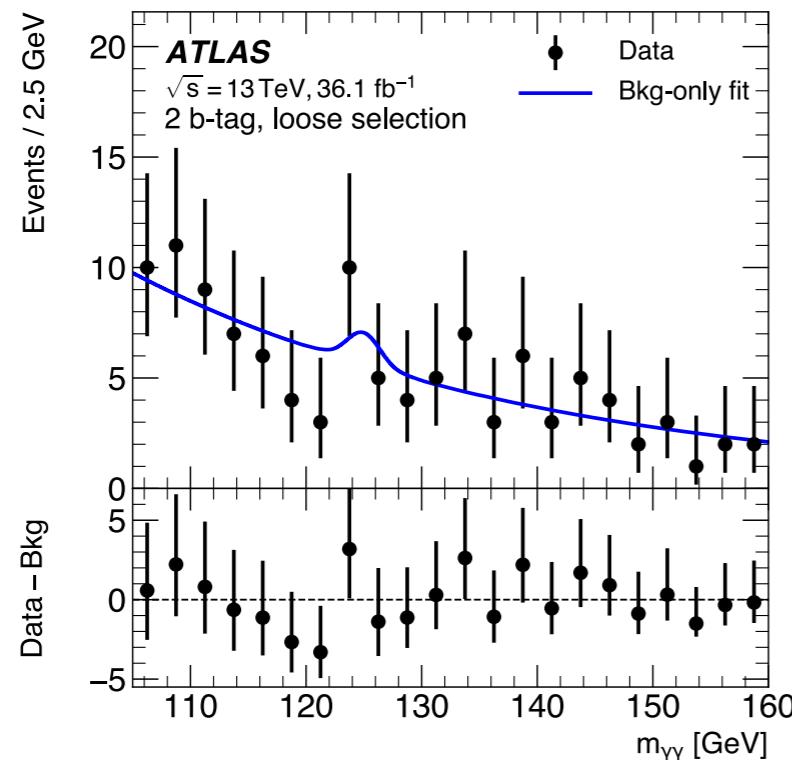

# Higgs boson pair production (2)

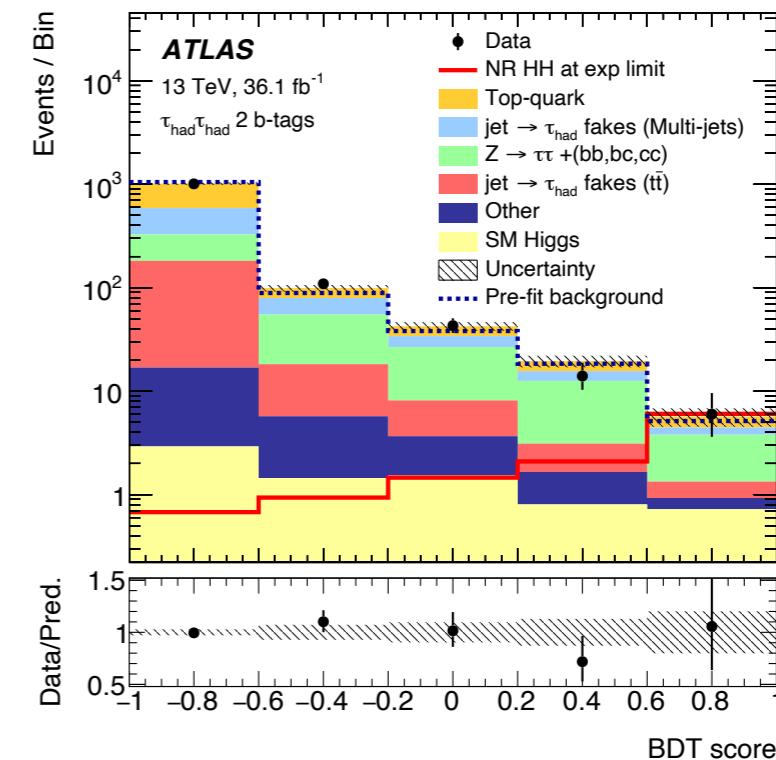

Tiny cross section ( $\sim 30 \text{ fb}$  in SM)  $\rightarrow$  need combination of (relatively) clean decay modes with sufficiently high branching fractions

- studied so far:  $b\bar{b}\gamma\gamma$ ,  $b\bar{b}\tau^+\tau^-$ ,  $b\bar{b}b\bar{b}$ ,  $b\bar{b}W^+W^-$ ,  $W^+W^-W^+W^-$ ,  $W^+W^-\gamma\gamma$
- generally complex analyses, but with large analysis dependence

fit  $m(\gamma\gamma)$  in  $b\bar{b}\gamma\gamma$  final state;  
use SM  $H(\rightarrow\gamma\gamma) + b\bar{b}$  prediction

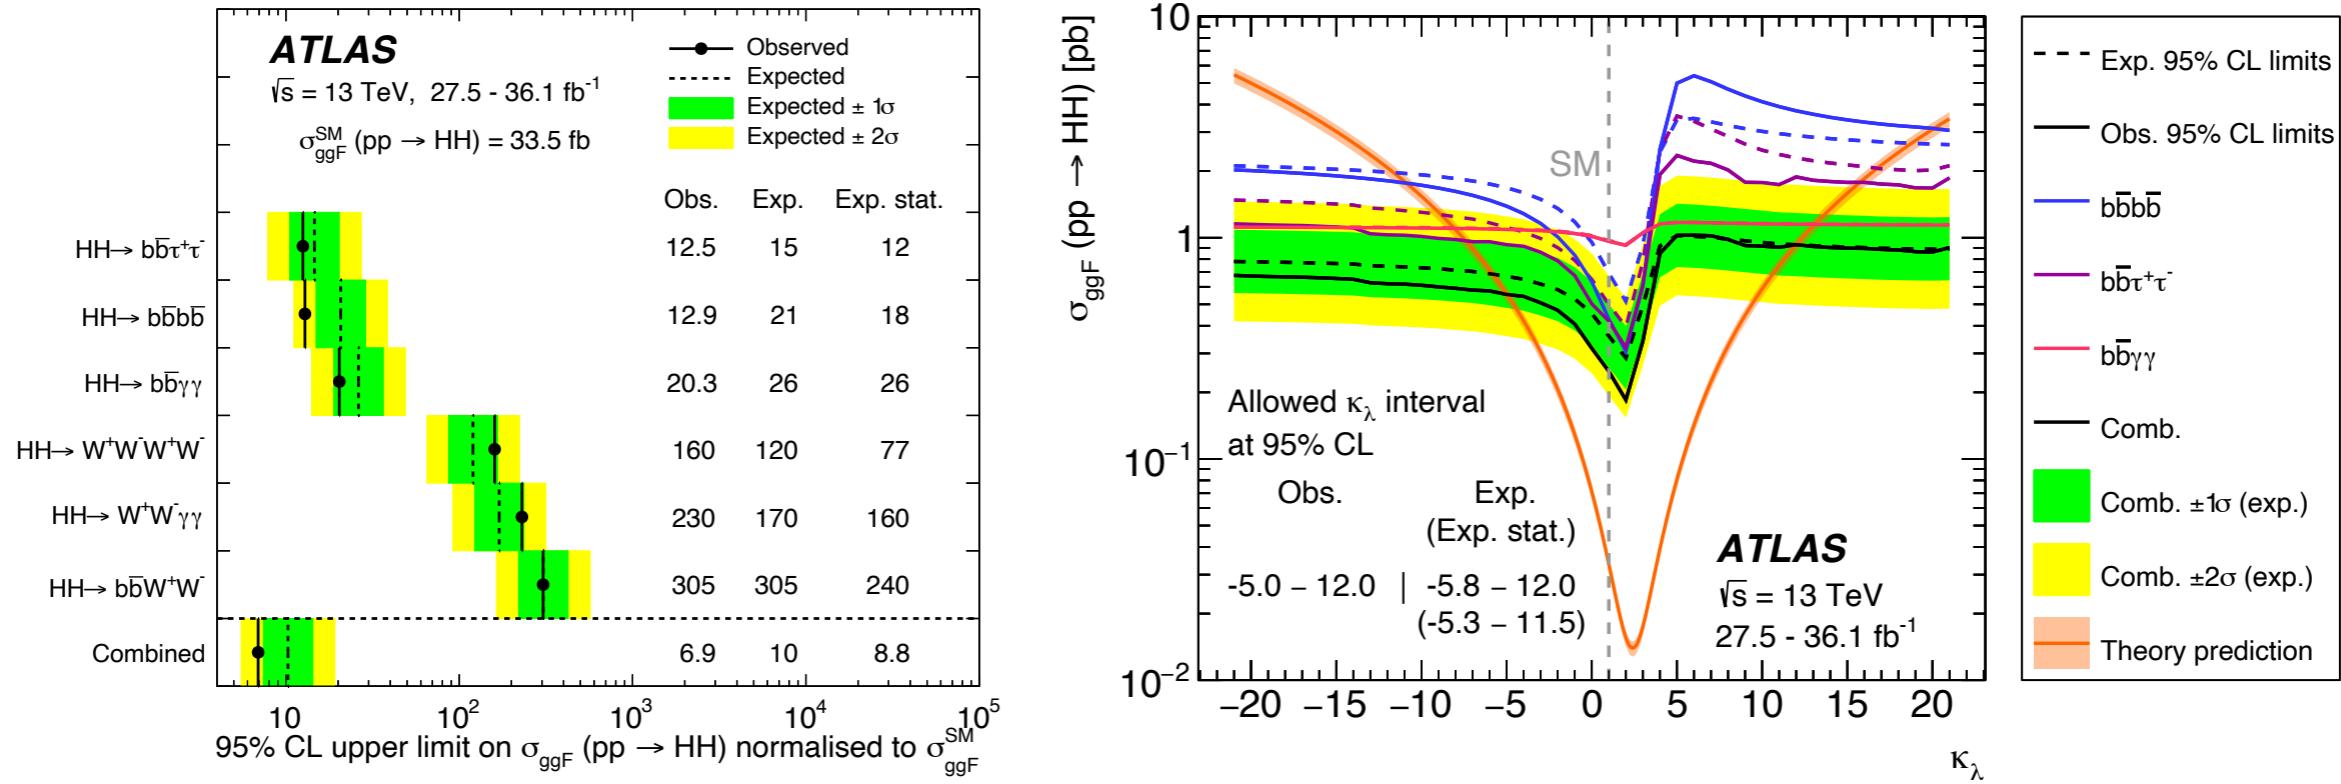

MVA in  $b\bar{b}\tau^+\tau^-$  final state,  
trained against  $t\bar{t}$  ( $\sim$  irreducible)

# Higgs boson pair production (2)

Tiny cross section ( $\sim 30 \text{ fb}$  in SM)  $\rightarrow$  need combination of (relatively) clean decay modes with sufficiently high branching fractions

- studied so far:  $b\bar{b}\gamma\gamma$ ,  $b\bar{b}\tau^+\tau^-$ ,  $bbb\bar{b}$ ,  $b\bar{b}W^+W^-$ ,  $W^+W^-W^+W^-$ ,  $W^+W^-\gamma\gamma$
- generally complex analyses, but with large analysis dependence

experimental cross section depends on  $\kappa_\lambda$  through event kinematics ( $m_{\text{HH}}$ )

Constraint  $-5 < \kappa_\lambda < 12$  weaker than from single-Higgs measurements

- but less model dependent

# The MSSM Higgs sector

The MSSM features 2 complex Higgs doublets  $H_u, H_d$

⇒ after symmetry breaking, 5 physical Higgs bosons:  $h, H, A, H^\pm$

Neutral Higgs boson modified couplings to SM particles:

| SM particle type             | $h$ coupling                      | $H$ coupling                     | $A$ coupling |
|------------------------------|-----------------------------------|----------------------------------|--------------|
| up-type quarks               | $\frac{\cos \alpha}{\sin \beta}$  | $\frac{\sin \alpha}{\sin \beta}$ | $\cot \beta$ |
| down-type quarks, $\ell^\pm$ | $-\frac{\sin \alpha}{\cos \beta}$ | $\frac{\cos \alpha}{\cos \beta}$ | $\tan \beta$ |
| $W, Z$ bosons                | $\sin(\beta - \alpha)$            | $\cos(\beta - \alpha)$           | 0            |

- $\tan \beta \equiv v_u/v_d$  (vevs)
- mixing angle  $\alpha$  diagonalises neutral Higgs boson mass matrix

Lightest CP-even Higgs boson  $h$  has  $m_h < M_Z$  at tree level, only SUSY radiative corrections can make it heavier:

$$\bullet m_h^2 \lesssim M_Z^2 \cos^2 2\beta + \frac{3g^2 m_t^4}{8\pi^2 M_W^2} \left( \ln(M_S^2/m_t^2) + \frac{X_t^2}{M_S^2} (1 - X_t^2/12M_S^2) \right), \quad X_t \equiv A_t - \mu \cot \beta$$

- $\mu: H_u - H_d$  interaction
- $A_t$ : tri-linear coupling
- $M_S$ : SUSY breaking scale

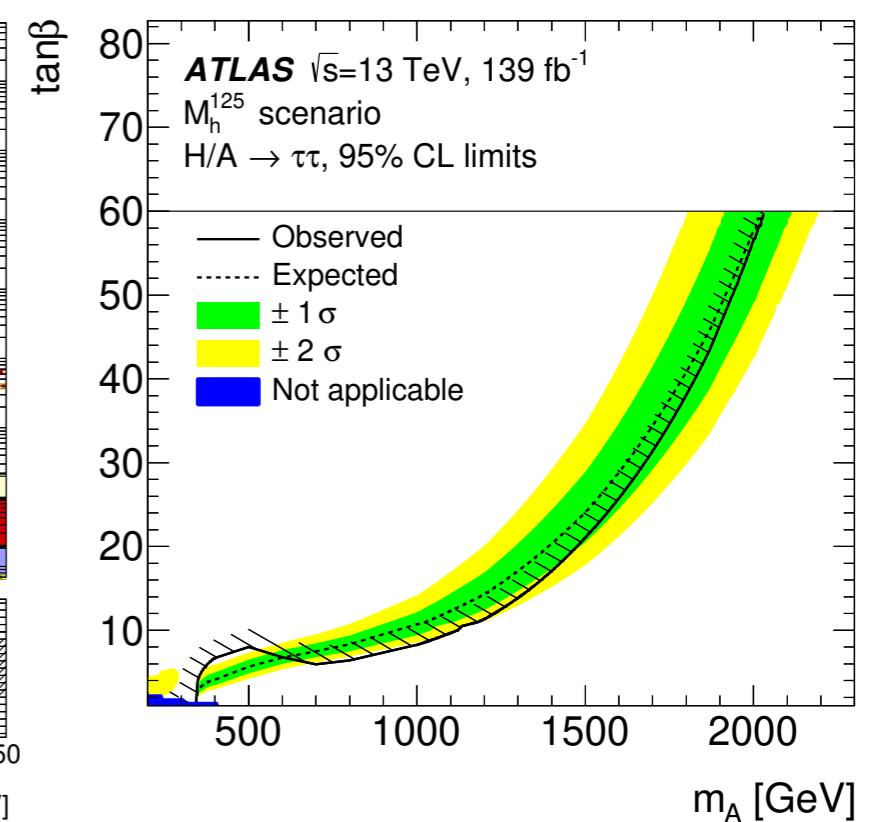

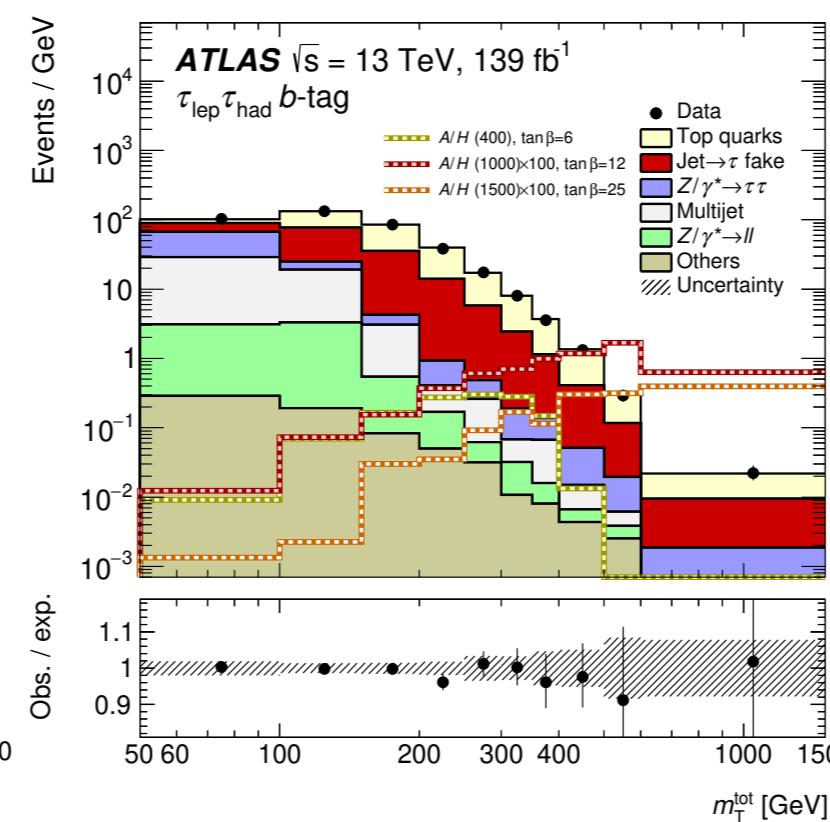

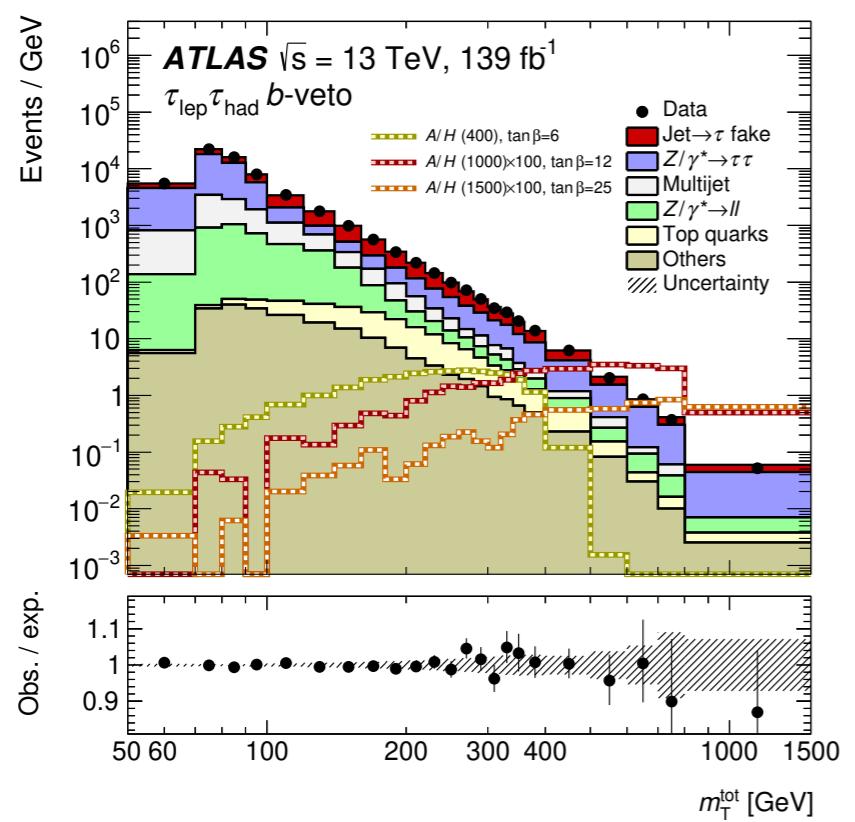

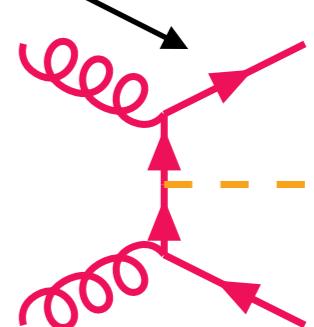

- ⇒ hMSSM: SUSY parameters tuned for  $m_h = 125$  GeV
- effective description just in terms of  $m_A$ ,  $\tan \beta$
  - decoupling limit: for  $m_A \gg M_Z$ ,  $h$  becomes SM-like

# Neutral MSSM Higgs boson searches

Searches for  $H, A$  focused mostly on high  $\tan\beta$  (motivated by LEP)  
 ➔ enhanced couplings to down-type quarks, charged leptons

- cleanest:  $H/A \rightarrow \tau^+\tau^-$ , produced in gluon fusion or  $b\bar{b} + H/A$
- high  $\tan\beta$  ➔  $m_H \approx m_A$  and large  $\Gamma$  ➔ seen as single resonance

Huge reduction in allowed  $\tan\beta$  range compared to  
 Run 1 results

# Charged MSSM Higgs boson searches

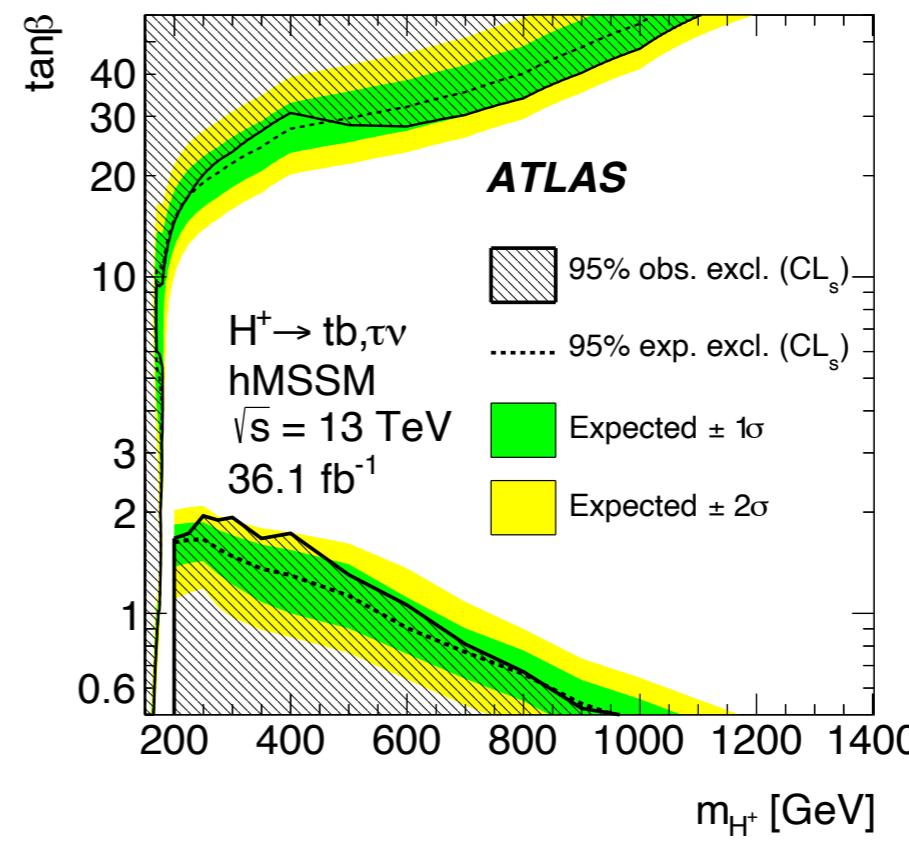

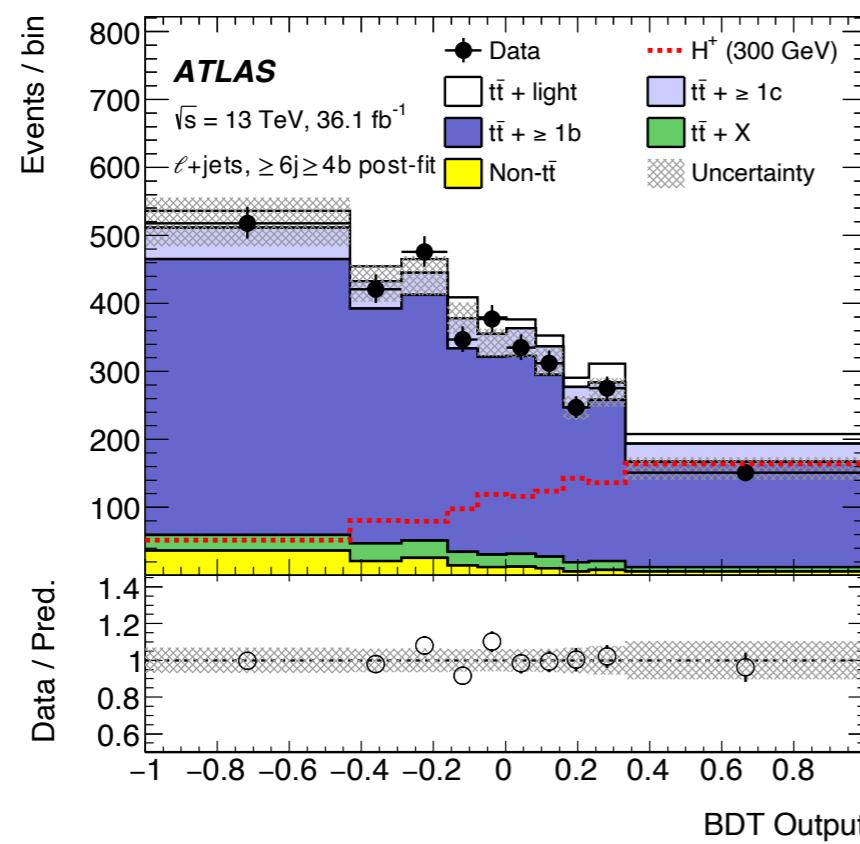

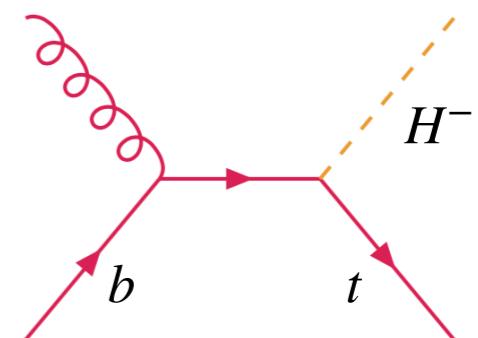

Charged Higgs boson coupling to fermions (e.g.  $t\bar{b}$ ):

$$g_{Htb} = m_t \cot \beta \frac{1}{2}(1 + \gamma^5) + m_b \tan \beta \frac{1}{2}(1 - \gamma^5)$$

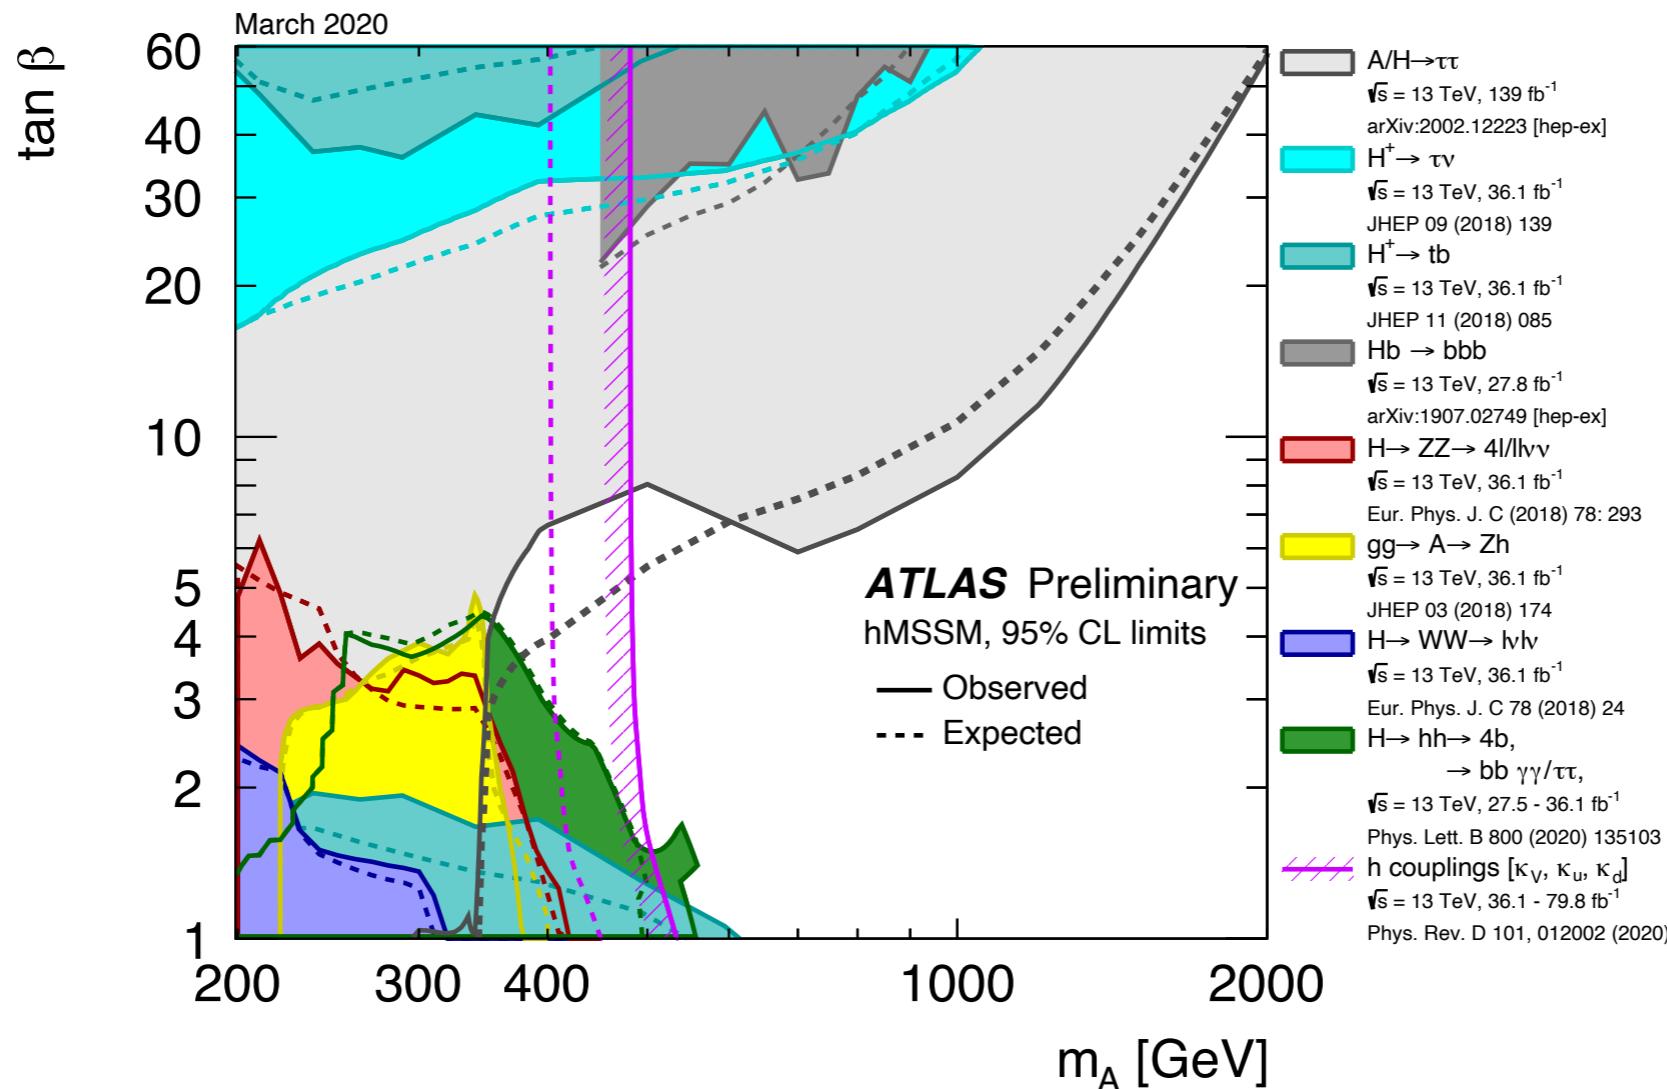

- sensitivity at both low and high values of  $\tan \beta$

Focus on high-mass  $H^- \rightarrow \bar{t}b$  ( $t\bar{t}b\bar{b}$  final state)

- alternative:  $H^- \rightarrow \tau^- \bar{\nu}_\tau$  (and also  $B \rightarrow D^{(*)}\tau\nu$ )
- significant exclusion of low  $\tan \beta$  regime

# MSSM Higgs status

Many explicit searches, but also strong constraints from measurements of  $h$  couplings

- $m_A > 500$  GeV  $\rightarrow$  approaching decoupling limit: MSSM is being pushed where it does not want to go!

# Finally

Many topics (especially BSM Higgs physics) not discussed; e.g.

- decays of heavy Higgs bosons to  $W^+W^-$  or  $ZZ$ ,  $A \rightarrow Zh$
- NMSSM (additional, possibly very light) Higgs bosons
- lepton flavour violating Higgs boson decays
- other BSM models involving couplings to Higgs bosons

LHC luminosity will increase further

- challenges for precision Higgs physics (especially couplings measurements) but plenty of improvements are still possible
- techniques optimised for the heaviest new (Higgs) particles
