

Finesse 3

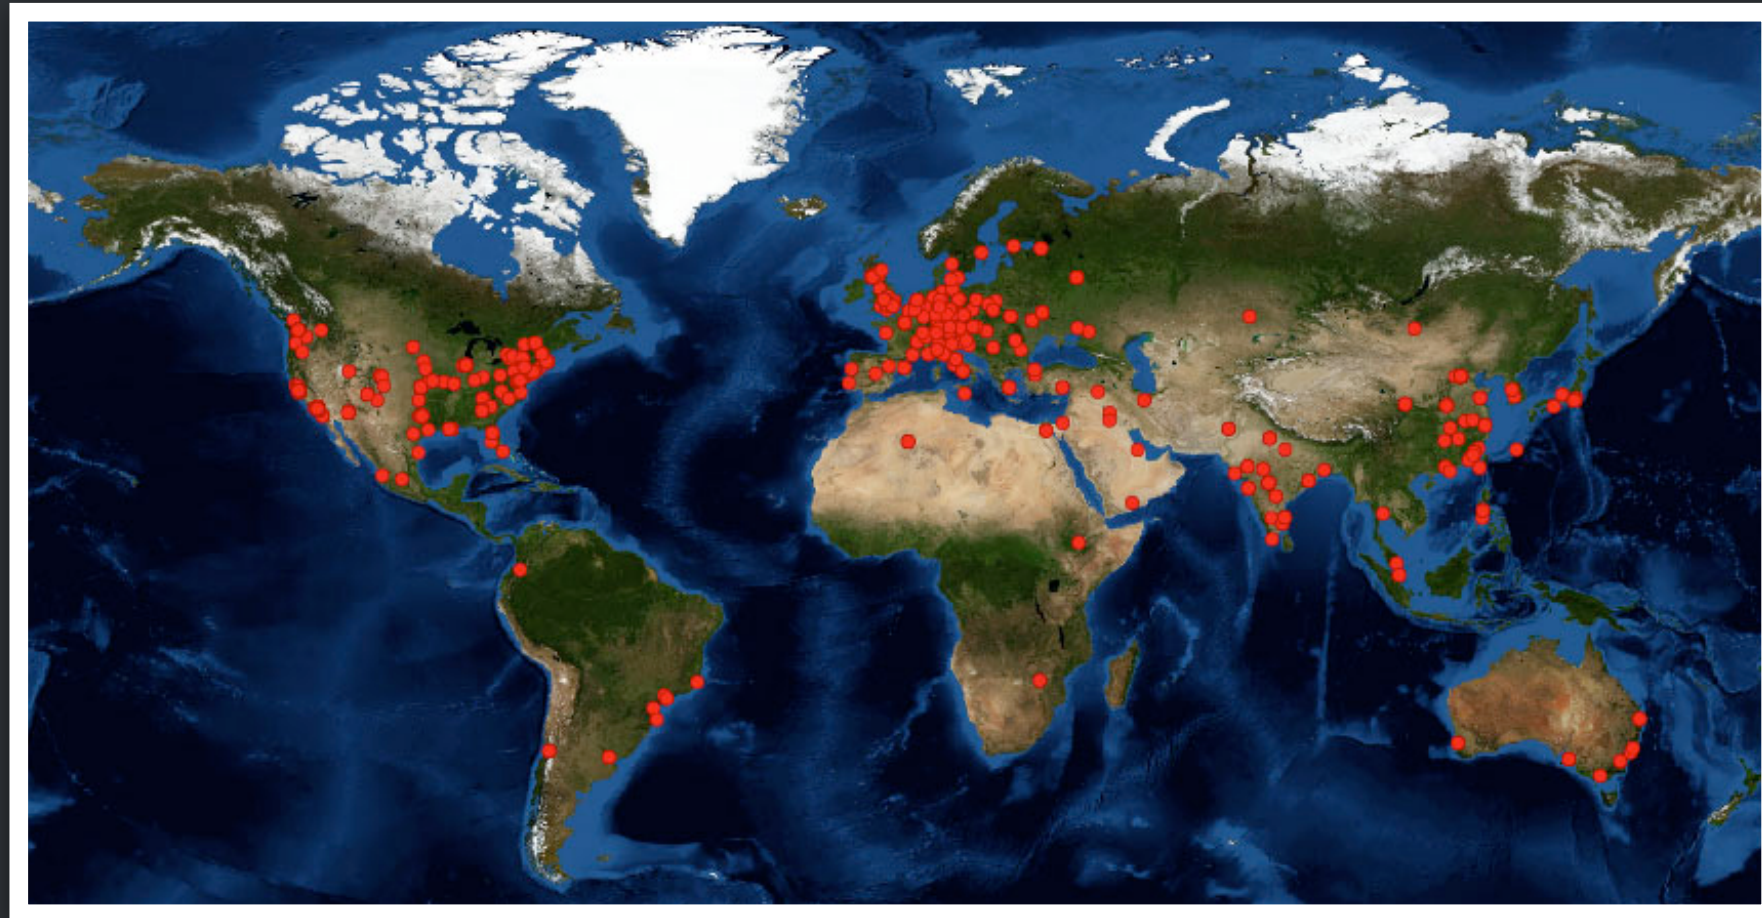

the new generation

a short introduction to our latest
version of FINESSE

Daniel Brown, Andreas Freise for the Finesse team, 05.06.2023

Long history short

- Started 1997, PhD side project
- Used extensively worldwide
- Open sourced in 2012
- Continuously used and developed

What can FINESSE do?

FINESSE can simulate:

- Beam shapes
- Optical losses
- Quantum noise
- Squeezing
- Radiation pressure effects
- Diverse detectors
- Error signals
- Transfer functions

... so long as the model is frequency domain (i.e. static or quasi-static), paraxial, and suits modelling using a modal basis.

FINESSE 2.1
with Multimode Squeezing

Frequency domain Interferometer Simulation Software

FINESSE is a frequency domain modelling tool for optical experiments, specialised at gravitational wave laser-interferometry. It is free and open source, released under the GPL license.

PyKat

PyKat is a free Python interface and set of tools for running FINESSE and for performing stand alone optical calculations. It is specialised for automating advanced optical simulations that involves multiple FINESSE runs.

FINESSE can Simulate:

- Imperfect Beams
- Imperfect Optics
- Quantum Noise
- Squeezing
- Radiation Pressure Effects
- Parametric Instabilities
- Realistic Detectors

Multimode Squeezing

Squeezed vacuum in the fundamental mode that scatters into anti-squeezed higher order modes could reduce the positive effect of squeezing. A suggested method to reduce this problem is to inject squeezed higher order modes with an angle such that the harmful anti-squeezing is reduced.

FINESSE in Commissioning and Design

FINESSE is being actively used in aLIGO commissioning modelling. We have a complete file of the interferometer as in the design documents, as well as variants specific to the Livingston and Hanford sites. The core file is tuned to the operating point and locked using PyKat to automate much of the process.

We are working on Active Wavefront Control (AWC) to improve detectors beyond aLIGO.

Parametric Instability Modelling

Parametric instability (PI) modelling been implemented in FINESSE, and this model has been successfully tested against the experimental results obtained by Corbitt *et al.* [1].

We have modelled PI for a LIGO arm using the mechanical mode thought to cause the PI seen in LIGO Livingston.

We are numerically investigating ways of suppressing PI, currently by using an extraction cavity.

Self-Study and Reference Material on Laser Interferometry

We offer free self-study material on laser optics, FINESSE and PyKat, in both HTML and Ipython/Jupyter Notebook formats. The material is aimed at beginners, but also functions as reference material for advanced users. Ipython/Jupyter Notebook offers a new transparent way of presenting simulations and scientific results that we will use frequently in the time to come.

gwoptics.org/learn

The figure shows the quantum noise dependence on mismatches between the filter cavity (FC), and the interferometer (IFO) and squeezer, which are matched to each other [2]. Here we looked at LIGO+ with a filter cavity [3] to produce frequency dependent squeezing. There is a clear improvement in spectrality, which degrades for low frequencies with the mismatch.

Upper left: Finesse model vs. the experiment by Corbitt *et al.* [1]. Upper right: Parametric gain in a model LIGO arm using the mechanical mode thought to cause PI in LLO, and the higher order modes thought to be involved. Lower left: Parametric gain in a model LIGO arm with an added extraction cavity. Lower right: Parametric gain in an arm of an LLO model for different TIMY radii of curvature.

Using FINESSE: match simulation to **defective** interferometers

The FINESSE team always spend significant effort to model imperfect interferometers. This was not yet crucial for the first generation of detectors, but has become essential for current and future instruments. Many FINESSE features, conventions and habits have been designed with this in mind.

Modal model (Finesse)

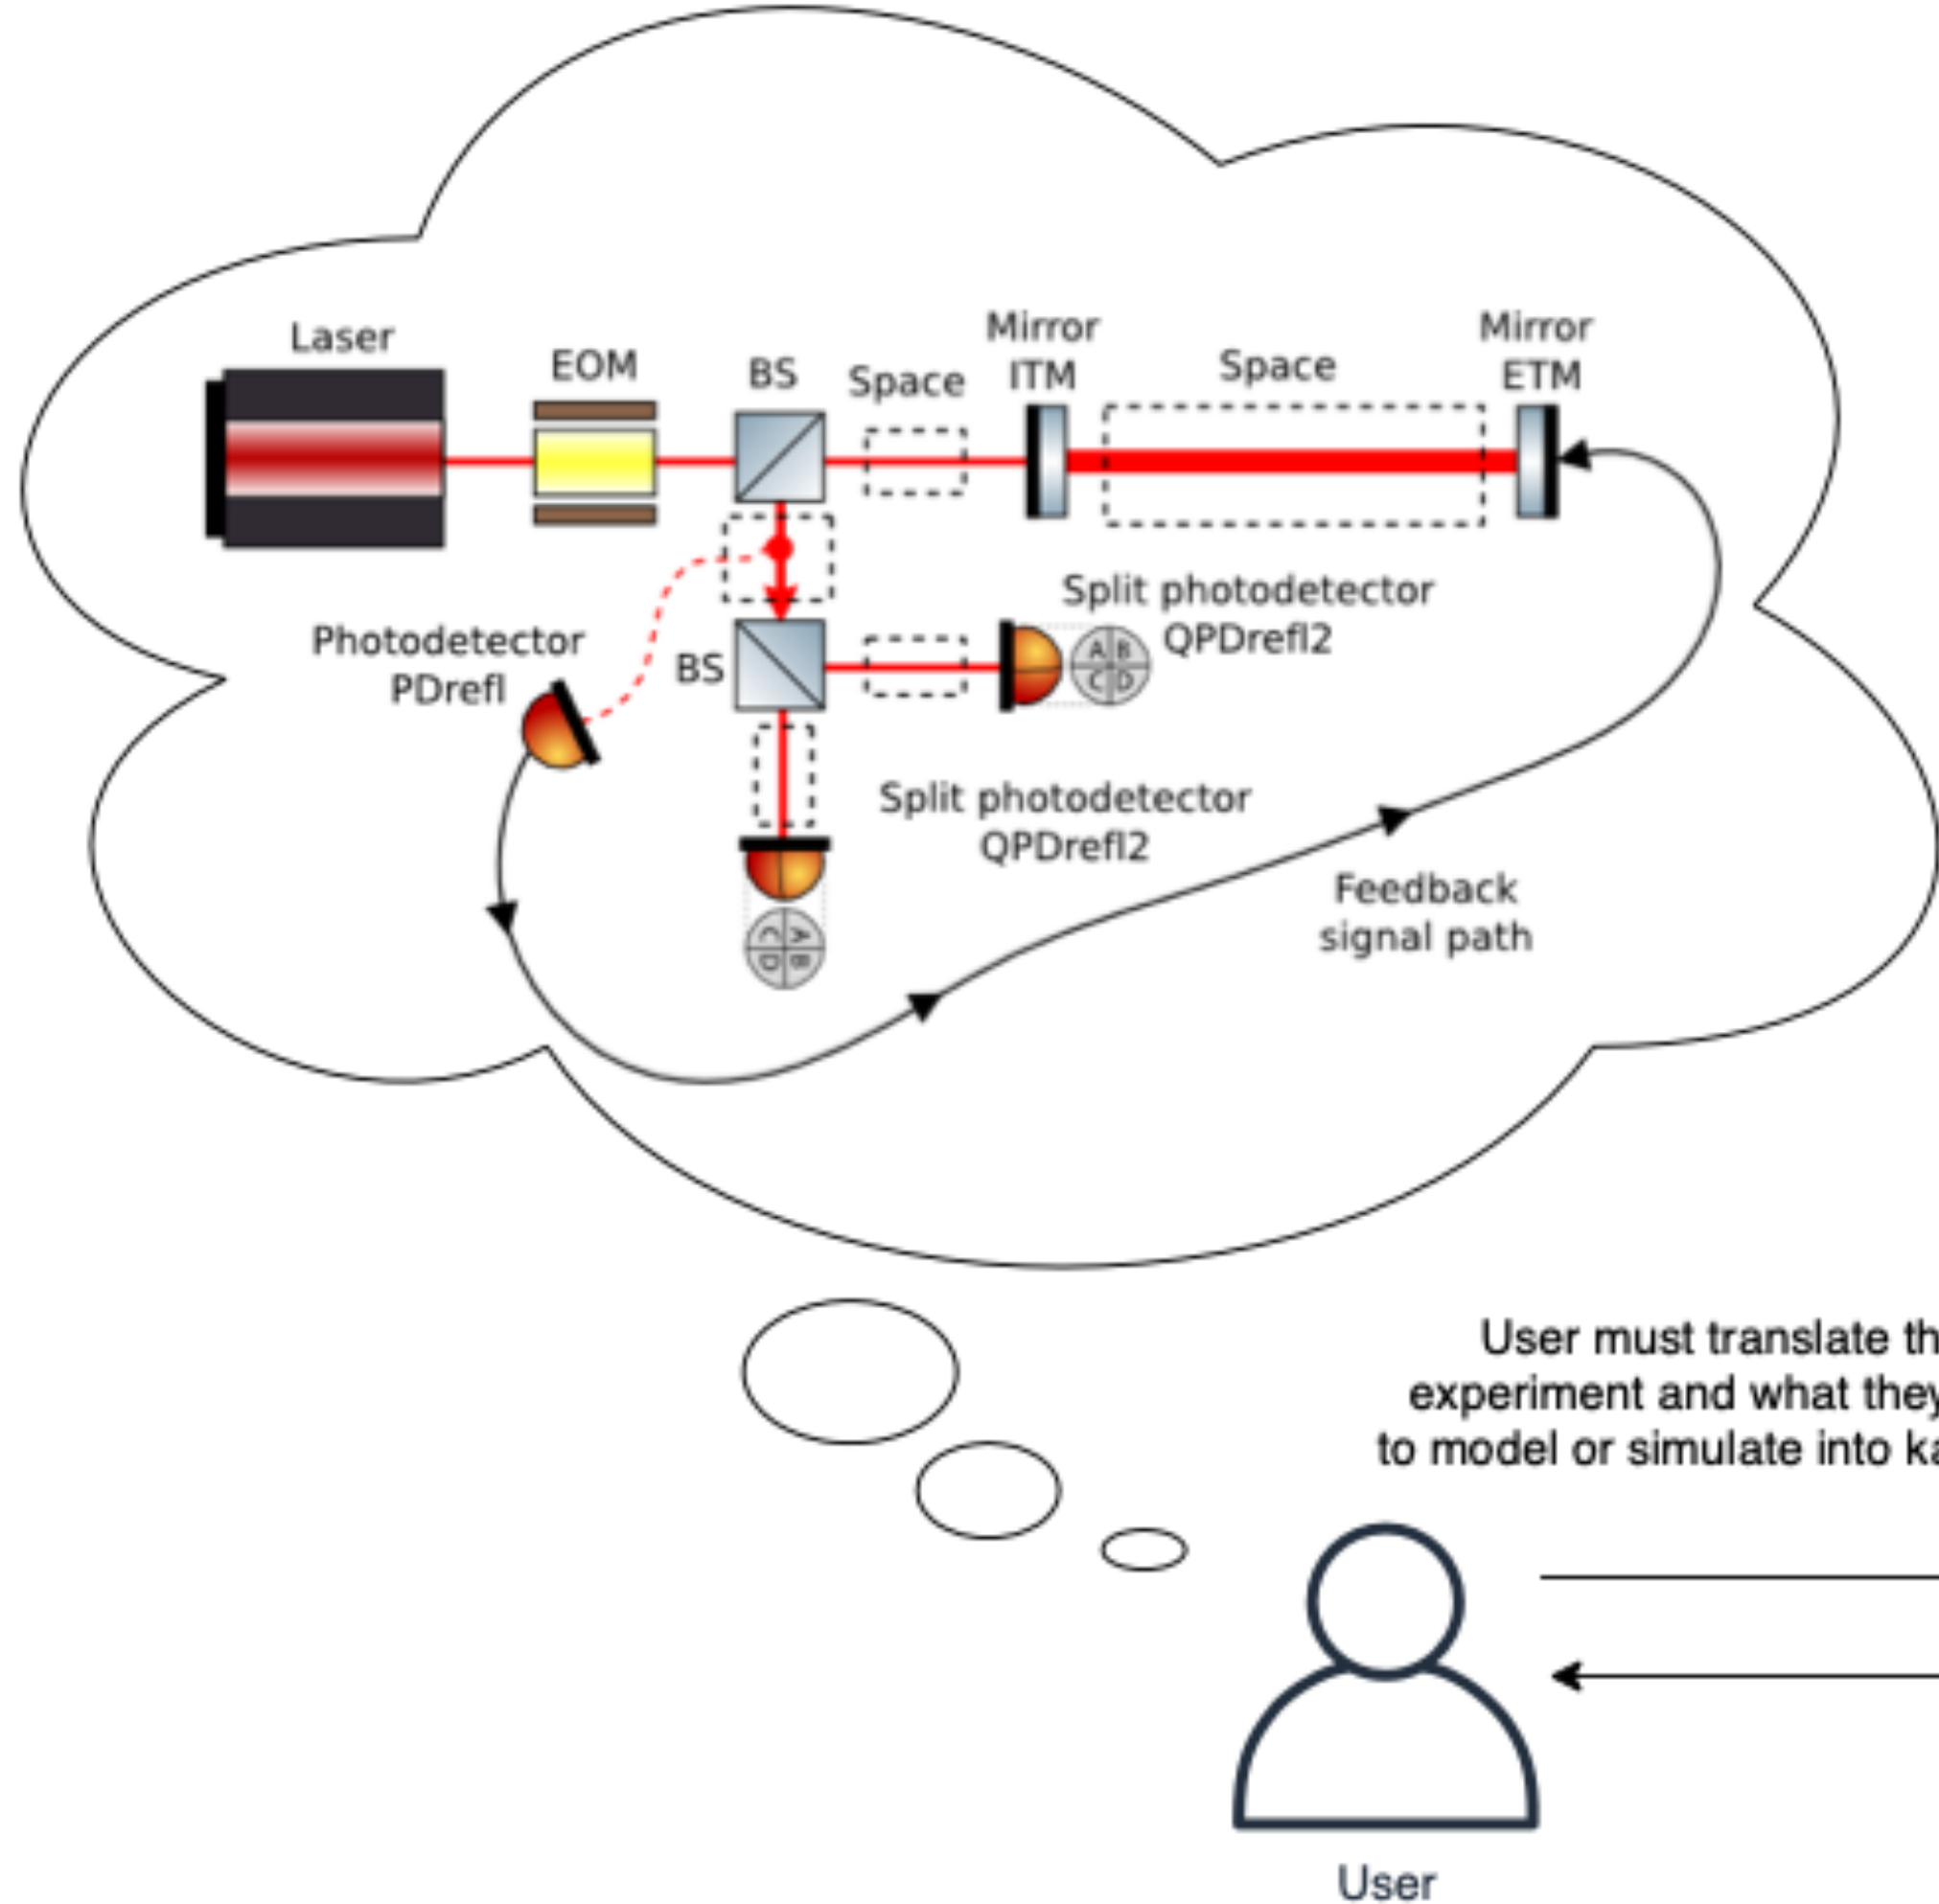

FFT propagation model (DarkF)

[J. Marque et al 2009]

FINESSE 2 + Pykat

FINESSE 3

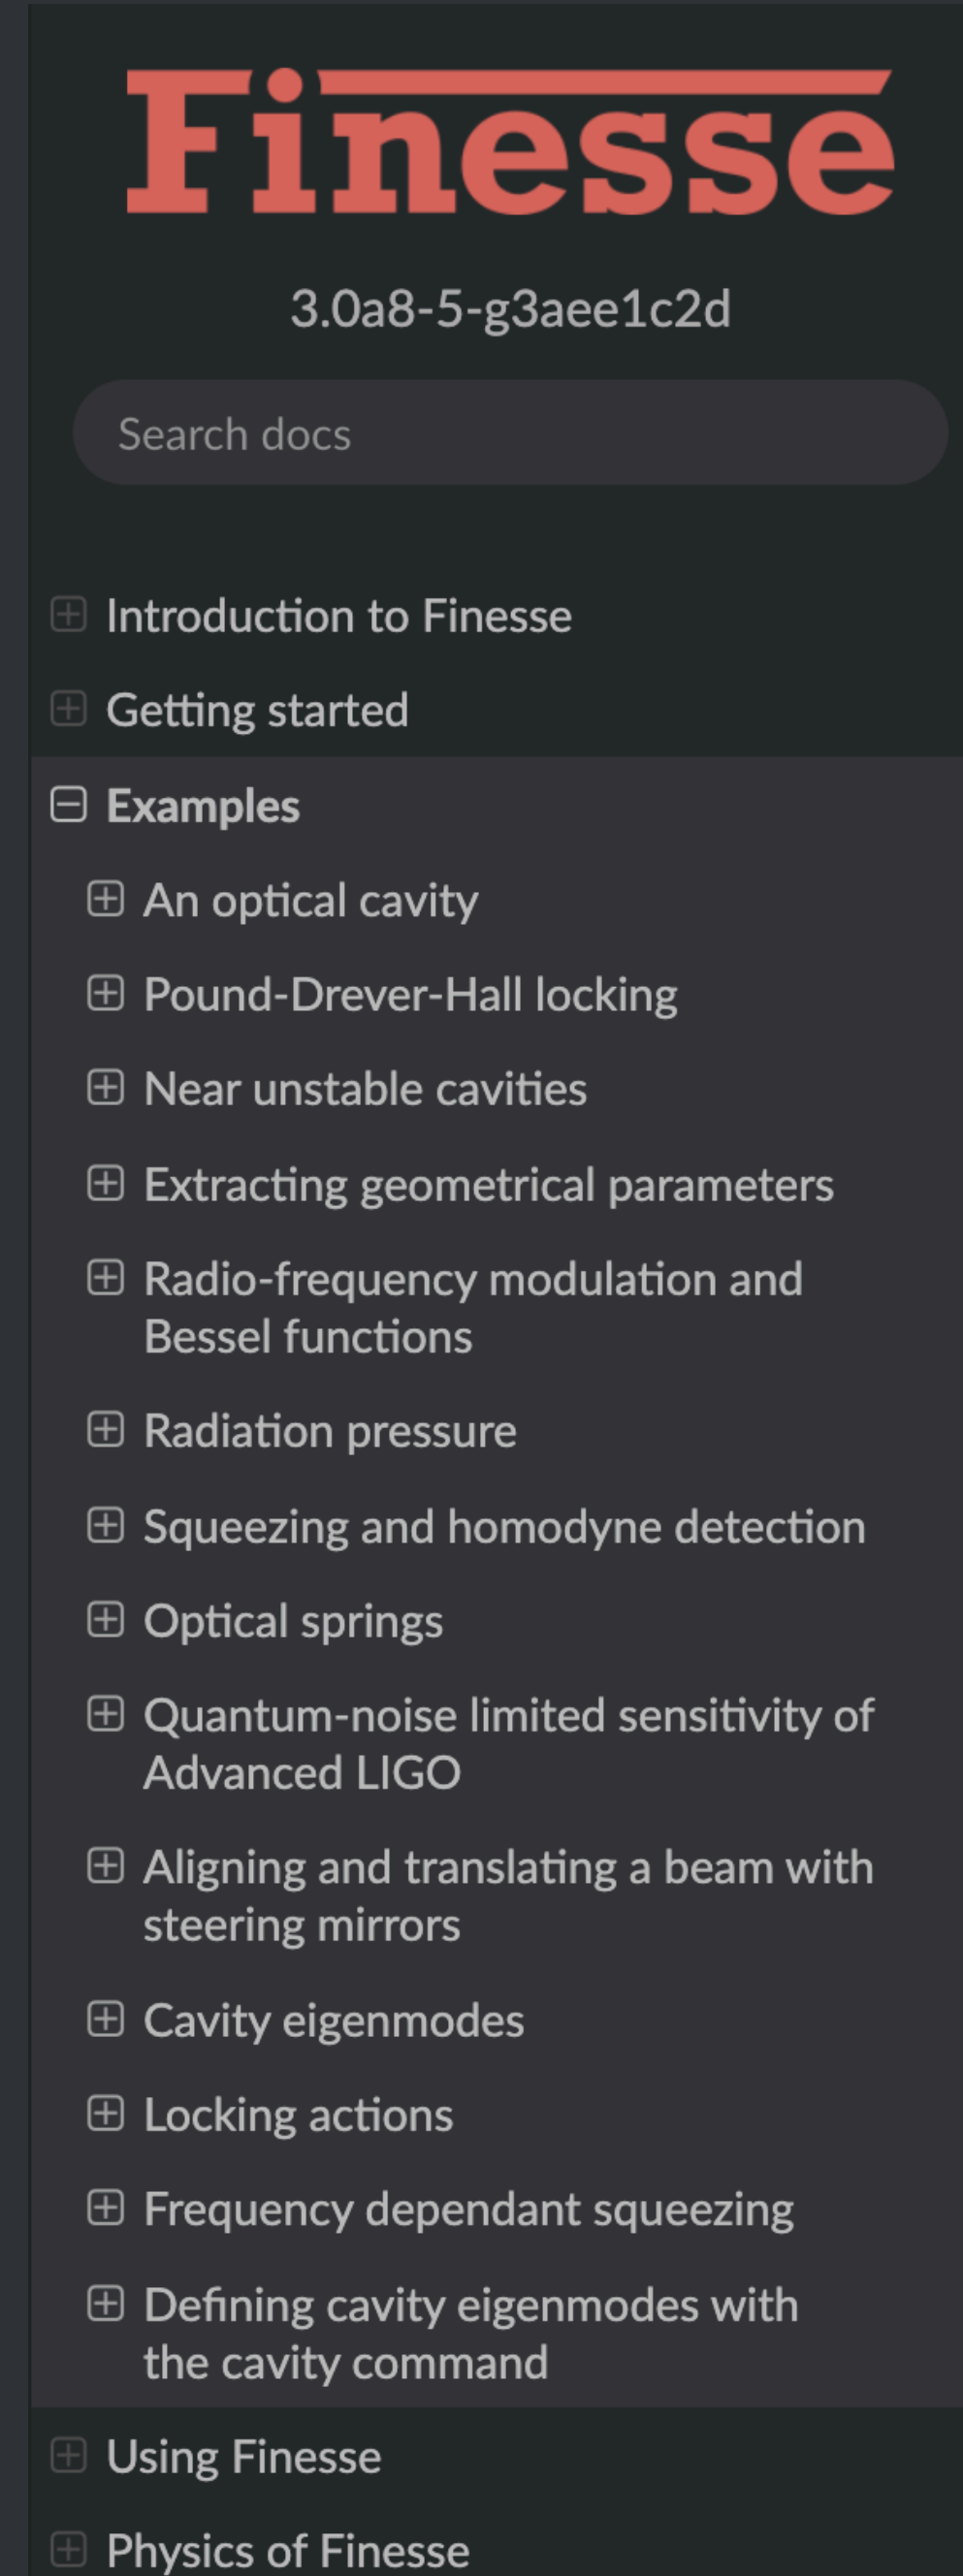

Combines both FINESSE 2 and Pykat for efficiency and performance

We are now encouraging the use of FINESSE 3 over previous versions!

The new FINESSE manual is not yet fully complete but is constantly evolving on the web page.

It contains many examples and documentation for various functions and commands.

If a part of the manual is not yet complete and you really need it, ask in the chat channel and we will aim to fill it in faster.

The screenshot shows the Finesse documentation website. At the top, the word "Finesse" is written in a large, stylized red font. Below it, the version number "3.0a8-5-g3aee1c2d" is displayed. A search bar with the placeholder text "Search docs" is present. A navigation menu on the left side lists various sections: "Introduction to Finesse", "Getting started", "Examples", "Using Finesse", and "Physics of Finesse". The "Examples" section is expanded, showing a list of topics such as "An optical cavity", "Pound-Drever-Hall locking", "Near unstable cavities", "Extracting geometrical parameters", "Radio-frequency modulation and Bessel functions", "Radiation pressure", "Squeezing and homodyne detection", "Optical springs", "Quantum-noise limited sensitivity of Advanced LIGO", "Aligning and translating a beam with steering mirrors", "Cavity eigenmodes", "Locking actions", "Frequency dependant squeezing", and "Defining cavity eigenmodes with the cavity command".

First Install

This section provides information on getting started with your first installation of FINESSE. Although other installation methods are available, we recommend following this guide to set up your initial environment to avoid known issues.

Python Installation

We recommend using Miniconda to install the Python ecosystem. We have created Conda packages to automate and easily install FINESSE in one command.

From the section titles, pick the one that suits your condition.

[I am a Python user and have Anaconda/Conda installed already \(Windows, OSX, or Linux\)](#)

[I am a Python user and have my own environment already set up that I want to use](#)

[For Windows users without Conda installed](#)

[For MacOS users without Conda installed](#)

[For Linux users without Conda installed](#)

I am a Python user and have Anaconda/Conda installed already (Windows, OSX, or Linux)

If you already use Conda on your system, then installation is very easy! You can proceed to [Installing Finesse and Jupyter with Conda](#).

Python vs KatScript

- FINESSE 2 only worked with **KatScript** (which limited what could be done).
- PyKat added a Python wrapper which essentially wrote **KatScript** for you.
- FINESSE 3 is firstly a Python program, it has a Python interface for everything. **KatScript** is a wrapper around the full Python programming interface.
- This means that you can use both to make models and run simulations. **KatScript** is often easier or more compact, Python is more powerful.
- Some features are not (yet) supported in **KatScript** and can only be used through Python (e.g surface maps).

```
model = finesse.script.parse("""  
laser l1 P=1  
space s1 l1.p1 m1.p2  
mirror m1 R=0.5 T=0.5  
power_detector_dc P m1.p2.o  
""")
```

KatScript

```
# or you can use a Python interface...  
from finesse.components import Laser, Space, Mirror  
from finesse.detectors import PowerDetector
```

```
model_python = finesse.Model()  
model_python.add(Laser('l1', P=1))  
model_python.add(Mirror('m1', R=0.5, T=0.5))  
model_python.add(  
    PowerDetector(  
        'P',  
        model_python.m1.p2.o  
    )  
)  
model_python.add(Space(  
    's1',  
    model_python.l1.p1,  
    model_python.m1.p1  
)  
)  
)
```

```

Changes to KatScript

FINESSE 3

- Main syntax style stays the same, i.e. m=mirror, one line per component
- No 'attribute' command any more
- Values are always assigned using the parameter name
- No need to specify nodes explicitly
- Instead spaces connect components directly (using 'ports')

```
m PRAR R=0.0 L=160u Rc=-3.62
s sPRsub PRAR.p2 PR.p1 L=0.1003 nr=nsilica
m PR T=0.04835 L=30u Rc=-1430.0

# Space between PR and POP. Length from TDR.
s lPR_POP PR.p2 POP_AR.p1 L=0.06

# Pick off plate. The angle of incidence and the physical distance
# propagates inside POP are computed from thickness of 3.5 cm
# tilt [TDR]. POP AR is wedged, thus one AR-reflectivity is set
# POP reflectivities [VIR-0027A-15]

bs POP_AR R=0.0 L=125u alpha=6.0

s sB4_att POP.p4 B4_attenuator.p1
bs B4_attenuator R=0.7344 T=0.2656
```

Changes to KatScript

FINESSE 3

- You can do math with numbers, variables and references in every command
- New 'degree of freedom' (dof) command
- New `readout' commands to work with `dof' for sensing matrices and noise projection

```
# Useful frequencies
#####
var fsrN (0.5 * c0 / LN.L)
var fsrW (0.5 * c0 / LW.L)
var fsrPRC (0.5 * c0 / lPRC)
var fsrSRC (0.5 * c0 / lSRC)
var f1_arm (125.5 * fsrN - 300.0) # Definition of f1, TDR section 2.3
var f1_SRC (3.5 * fsrN)
var f1_PRC (3.5 * fsrN)

```

Actions

FINESSE 3

- `Actions` are new Python functions to run FINESSE tasks.
- The actions pre-define all task before they are run. This allows FINESSE 3 to optimise the model (i.e. remove all tuning options that are not required by any action).
- Each action can do either a single simple task or execute a complex task.
- Most users would just use existing actions, but they are easy to write/expand with a bit of Python knowledge.

```
self.model.run(  
    Series(  
        # Switch off the modulators and remove SR and PR by misaligning them.  
        Change(  
            {"eom6.midx": 0, "eom8.midx": 0, "eom56.midx": 0,  
             "SR.misaligned": True, "PR.misaligned": True,  
             "SRAR.misaligned": True, "PRAR.misaligned": True,  
            }  
        ),  
        # Maximize arm power  
        Maximize("B7_DC", "NE_z.DC", bounds=[-180, 180], tol=1e-14),  
        Maximize("B8_DC", "WE_z.DC", bounds=[-180, 180], tol=1e-14),  
        # Minimize dark fringe power  
        Minimize("B1_DC", "MICH.DC", bounds=[-180, 180], tol=1e-14),  
        # Bring back PR  
        Change({"PR.misaligned": False}),  
        # Maximize PRC power  
        Maximize("CAR_AMP_BS", "PRCL.DC", bounds=[-180, 180], tol=1e-14),  
        # Bring in SR  
        Change({"SR.misaligned": False}),  
        # Maximize SRC power  
        # B4_112 requires 56MHz  
        Change({"SRCL.DC": 0, "eom56.midx": midx}),  
        Maximize("B4_112_mag", "SRCL.DC", bounds=[-180, 180], tol=1e-14),  
    ),  
)
```

Nodes and ports

Nodes are quite different in FINESSE 3! Each component can have multiple *ports*, each port has multiple *nodes*.

How many and what nodes there are at a **port** depends on the physical type: *Optical* or *Signal*.

Optical nodes have an input and an output, optical fields can travel in both directions. Optical ports are typically named `pN` where N is the node number, pN.i and pN.o are the input and output optical fields from the component.

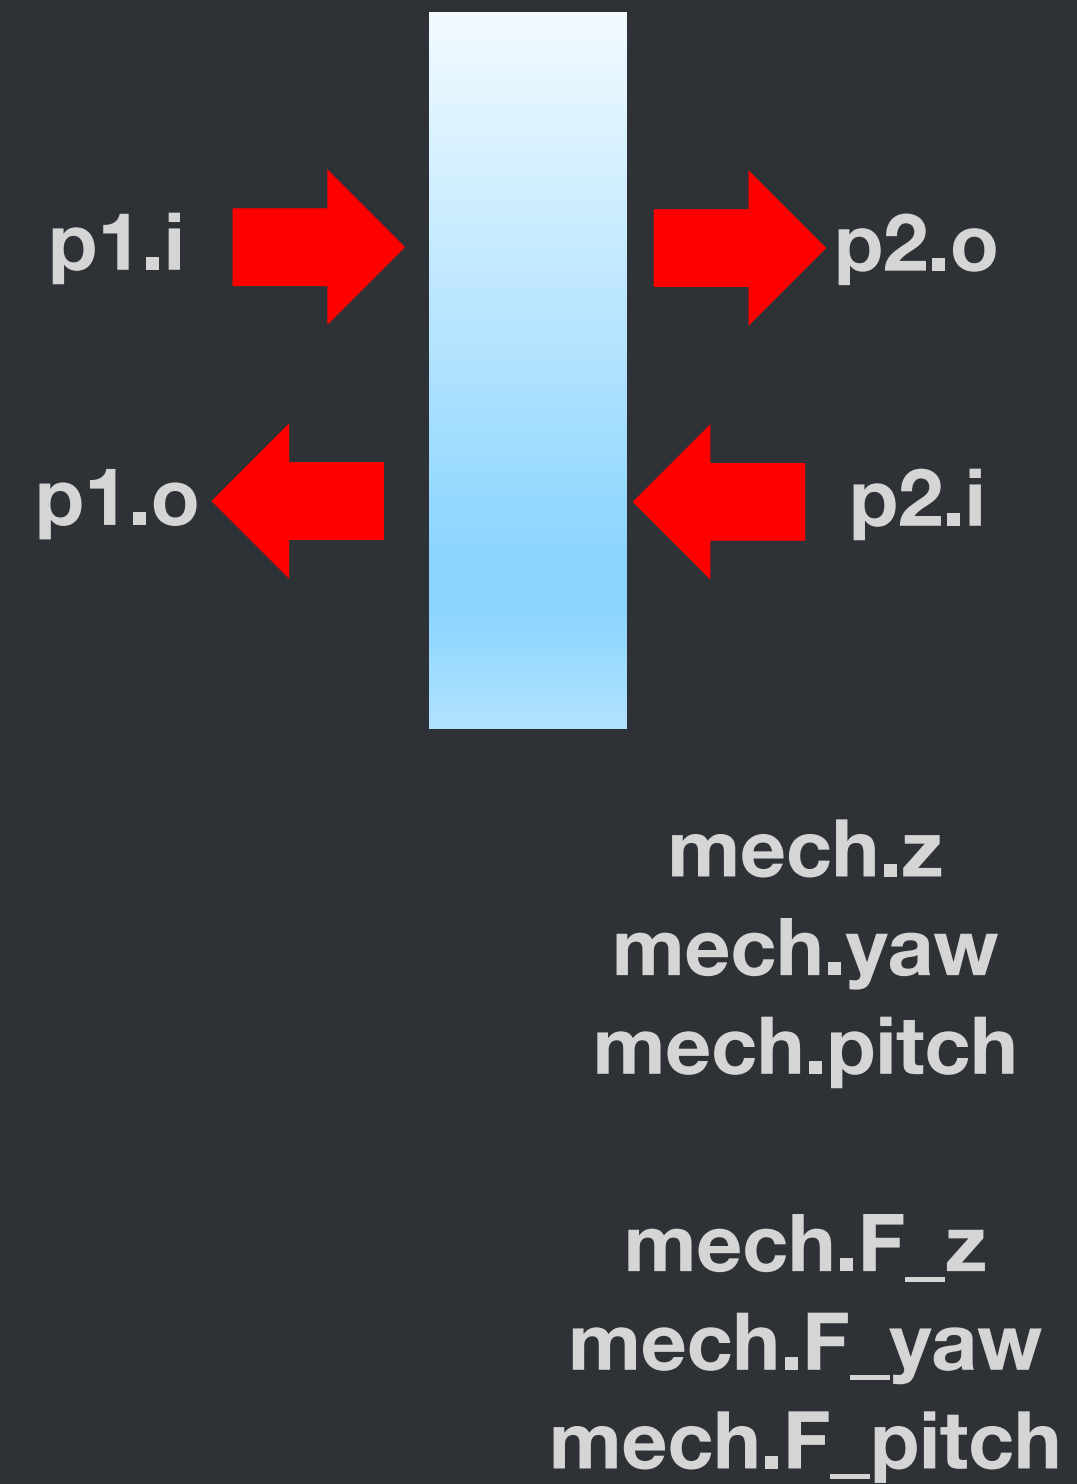

Signal nodes represent electrical or mechanical states in the system (these are where you can inject and read signals from, like a GW signal or a small mirror oscillation).

```
model = finesse.script.parse("""  
laser l1 P=1  
""")  
model.l1.nodes
```

✓ 0.0s

```
OrderedDict([('l1.p1.i', <OpticalNode l1.p1.i @ 0x1678eb8b0>),
