

5 Standard Library – Using I/O streams

© 2006 Wouter Verkerke, NIKHEF

242

Introduction

- The Standard Library organizes all kinds of I/O operations through a standard class `iostream`
- We've already used class `iostream` several types through the objects `cin` and `cout`

```
#include <iostream>
using namespace std ;

int main() {
    double x;

    // Read x from standard input
    cin >> x ;

    // Write x to standard output
    cout << "x = " << x << endl ;

    return 0 ;
}
```

- We will now take a better look at how streams work

243

A look behind the scenes

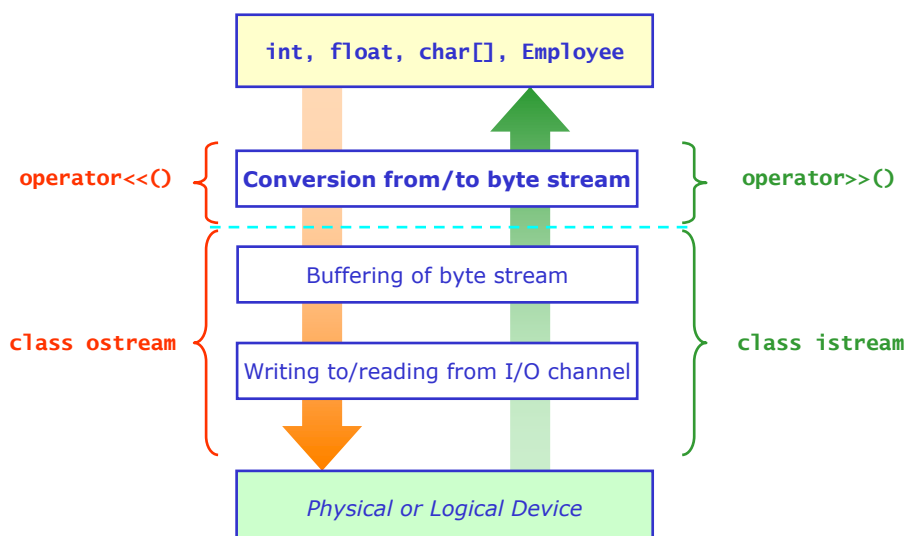

- I/O in C++ involves three distinct steps

244

I/O classes and operators in C++

- Operators `<<()`, `>>()` do step 1, classes `istream`, `ostream` do step 2

245

Stream object in the Standard Library

- Stream classes in Standard Library

| Include file | Logical or physical device | Direction of byte stream | | |
|--------------|----------------------------|--------------------------|----------------------|---------------------|
| | | Input | Output | Both |
| <iostream> | Generic (e.g.terminal) | istream | ostream | iostream |
| <fstream> | File | ifstream | ofstream | fstream |
| <sstream> | std::string | istringstream | ostringstream | stringstream |

- Standard Library stream classes also implement all operators to convert built-in types to byte streams
 - Implemented as member operators of stream class
 - Example: `ostream::operator<<(int) ;`
- Standard Library also provides three global stream objects for 'standard I/O'
 - `istream` object `cin` for 'standard input'
 - `ostream` objects `cout,cerr` for 'standard output','standard error'

246

Using streams without operators >>(),<<()

- Streams provide several basic functions to read and write bytes
 - Block operations

```
char buf[100] ;
int count(99) ;

// read 'count' bytes from input stream
cin.read(buf, count) ;

// write 'count' bytes to output stream
cout.write(buf, count) ;
```

© 2006 Wouter Verkerke, NIKHEF

247

Using streams without operators >>(),<<()

- Streams provide several basic functions to read and write bytes

- Line oriented operations

```
// read line from stdin up to and including the newline char
cin.get(buf,100) ;
```

```
// read line from std up to newline char
cin.getline(buf,100) ;
```

```
// read line up to and including ':'
cin.get(buf,100,':') ;
```

```
// read single character
cin.get(c) ;
```

```
// write buffer up to terminating null byte
cout.write(buf,strlen(buf)) ;
```

```
// write single character
cout.put(c) ;
```

248

How is the stream doing?

- Member functions give insight into the *state* of the stream

| Function | Meaning |
|-------------|-------------------------------------|
| bool good() | Next operation <i>might</i> succeed |
| bool eof() | End of input seen |
| bool fail() | Next operation will fail |
| bool bad() | Stream is corrupted |

- Example – reading lines from a file till the end of the file

```
ifstream ifs("file.txt") ;
char buf[100] ;

// Loop as long as stream is OK
while(!ifs.fail()) {
    ifs.getline(buf,100) ;

    // Stop here if we have reached end of file
    if (ifs.eof()) break ;

    cout << "just read " << buf << " " << endl ;
}
```

249

Some handy abbreviations

- Streams overload operator `void*()` to return `!fail()`
 - Can shorten preceding example to

```
while(ifs) { // expanded to while(ifs.operator void*())
  ifs.getline(buf,100) ;
  if (ifs.eof()) break ;
  cout << "just read " << buf << "" << endl ;
}
```

- Also return value of `getline()` provides similar information

- Returns true if stream is good() and stream is not at eof() after operation

```
while(ifs.getline(buf,100)) {
  cout << "just read " << buf << "" << endl ;
}
```

250

Using stream operators

- The next step is to use the streaming operators instead of the 'raw' IO routines
 - Encapsulation, abstraction → let objects deal with their own streaming
- Solution: use `operator>>()` instead of `getline()`

shoesize.txt

```
Bjarne 42
Leif 47
Thor 52
```

```
ifstream ifs("shoesize.txt") ;
string name ;
int size ;

while(ifs >> name >> size) {
  cout << name << " has shoe size " << size << endl ;
}
```

© 2006 Wouter Verkerke, NIKHEF

251

Using stream operators

- Remember: syntax of stream operators is like that of any other operator

```
string name ;  
int size ;  
cin >> name >> size ;  
  
↓  
string name ;  
int size ;  
cin.operator>>( cin.operator>>(name), size) ;
```

- For all built-in types
 - `operator<<(ostream,TYPE)` and `operator>>(istream,TYPE)` are implemented as member functions of the streams
 - Special case: `operator<<(const char*)` and `operator>>(char*)` read and write `char[]` strings

© 2006 Wouter Verkerke, NIKHEF

252

Parsing input – some fine points

- Delimiters
 - How does the text line
`Bjarne Stroustrup 42`
map on to the statement
`cin >> firstName >> lastName >> shoeSize ;`
 - Because each `operator>>()` stops reading when it encounters 'white space'
 - White space is 'space', 'tab', 'vertical tab', 'form feed' and 'newline'
 - White space between tokens is automatically 'eaten' by the stream
- Reading string tokens
 - Be careful using `char[]` to read in strings: `operator>>(const char*)` does not know your buffer size and it can overrun!
 - Better to use `class string`

253

Formatting output of built-in types

- For built-in types streams have several functions that control formatting

- Example: manipulating the base of integer output

```
cout.setf(ios_base::oct,ios_base::basefield) ; // set octal
cout << 1234 << endl ; // shows '02322'
```

```
cout.setf(ios_base::hex,ios_base::basefield) ; // set hex
cout << 1234 << endl ; // shows '0x4d2'
```

- But it is often inconvenient to use this as calling formatting function interrupt chained output commands

- To accomplish formatting more conveniently streams have 'manipulators'

- Manipulators are 'pseudo-objects' that change the state of the stream on the fly:

```
cout << oct << 1234 << endl << hex << 1234 << endl ;
// shows '2322' '4d2'
```

© 2006 Wouter Verkerke, NIKHEF

254

Overview of manipulators

- So manipulators are the easiest way to modify the formatting of built-in types

- What manipulators exist?

- Integer formatting

| Manipulator | Stream type | Description |
|-----------------------------|-------------|--------------------------------|
| <code>dec</code> | iostream | decimal base for integer |
| <code>hex</code> | iostream | hexadecimal base for integer |
| <code>oct</code> | iostream | octal base for integer |
| <code>[no]showpos</code> | iostream | show '+' for positive integers |
| <code>setbase(int n)</code> | iostream | base n for integer |

- Floating point formatting

| Manipulator | Stream type | Description |
|----------------------------------|-------------|--|
| <code>setprecision(int n)</code> | iostream | show n places after decimal point |
| <code>[no]showpoint</code> | iostream | [don't] show trailing decimal point |
| <code>scientific</code> | iostream | scientific format <code>x.xxexx</code> |
| <code>uppercase</code> | iostream | print <code>0XFF</code> , <code>nnExx</code> |
| <code>fixed</code> | iostream | format <code>xxxx.xx</code> |

255

Manipulators – continued

- Alignment & general formatting

| Manipulator | Stream type | Description |
|------------------------------|-------------|--------------------------------------|
| <code>left</code> | iostream | align left |
| <code>right</code> | iostream | align right |
| <code>internal</code> | iostream | use internal alignment for each type |
| <code>setw(int n)</code> | iostream | next field width is n positions |
| <code>setfill(char c)</code> | iostream | set field fill character to c |

- Miscellaneous

| Manipulator | Stream type | Description |
|------------------------------|-------------|-------------------------------|
| <code>endl</code> | ostream | put '\n' and flush |
| <code>ends</code> | ostream | put '\0' and flush |
| <code>flush</code> | ostream | flush stream buffers |
| <code>ws</code> | istream | eat white space |
| <code>setfill(char c)</code> | iostream | set field fill character to c |

- Include `<iomanip>` for most manipulator definitions

© 2006 Wouter Verkerke, NIKHEF

256

Formatting output with manipulators

- Very clever, but how do manipulators work?
 - A manipulator is a 'pseudo-object' that modifies the state of the stream
 - More precisely: a manipulator is a *static member function* of the stream that takes a stream as argument, for example

```
class ostream {
    static ostream& oct(ostream& os) {
        os.setf(ios::oct, ios::basefield) ;
    }
};
```

- The manipulator applies its namesake modification to the stream argument
- You put manipulators in your print statement because class `ostream` also defines

```
operator<<(ostream&(*)(ostream&)) {
    return f(*this) ;
}
```

This operator processes any function that takes a single `ostream&` as argument and returns an `ostream`. The operator calls the function with itself as argument, which then causes the wanted operation to be executed on itself

257

Random access streams

- Streams tied to files and to strings also allow random access
 - Can move 'current' position for reading and writing to arbitrary location in file or string

| member function | stream | Description |
|--------------------------------|--------|---|
| <code>streampos tellg()</code> | input | return current location of 'get()' position |
| <code>seekg(streampos)</code> | input | set location of 'get()' position |
| <code>streampos tellp()</code> | output | return current location of 'put()' position |
| <code>seekp(streampos)</code> | output | set location of 'put()' position |

- Streams open for both input and output (`fstream`, `stringstream`) have all four methods, where `put()` and `get()` pointer can be in different positions

© 2006 Wouter Verkerke, NIKHEF

258

Random access streams

- Example use of `tell()`, `seek()`

```
#include <fstream>
// Open file for reading and writing
fstream iofile("file.dat", ios::in|ios::out) ;
```

259

Random access streams

- Example use of `tell()`, `seek()`

```
#include <fstream>

// Open file for reading and writing
fstream iofile("file.dat",ios::in|ios::out) ;

// Read in (fictitious) file header
FileHeader hdr ;
iofile >> hdr ;
```

260

Random access streams

- Example use of `tell()`, `seek()`

```
#include <fstream>

// Open file for reading and writing
fstream iofile("file.dat",ios::in|ios::out) ;

// Read in (fictitious) file header
FileHeader hdr ;
iofile >> hdr ;

// Store current location of stream 'get()' pointer
streampos marker = ifs.tellg() ;
```

261

Random access streams

- Example use of `tell()`, `seek()`

```
#include <fstream>

// Open file for reading and writing
fstream iofile("file.dat",ios::in|ios::out) ;

// Read in (fictitious) file header
FileHeader hdr ;
iofile >> hdr ;

// Store current location of stream 'get()' pointer
streampos marker = ifs.tellg() ;

// Read (fictitious) file data object
FileDataObj fdo ;
iofile >> fdo ;
```

262

Random access streams

- Example use of `tell()`, `seek()`

```
#include <fstream>

// Open file for reading and writing
fstream iofile("file.dat",ios::in|ios::out) ;

// Read in (fictitious) file header
FileHeader hdr ;
iofile >> hdr ;

// Store current location of stream 'get()' pointer
streampos marker = ifs.tellg() ;

// Read (fictitious) file data object
FileDataObj fdo ;
iofile >> fdo ;

// modify file data object

// Move current' location of stream
// 'put '()' pointer to marked position
ifs.tellp(marker) ;
```

263

Random access streams

- Example use of `tell()`, `seek()`

```
#include <fstream>

// Open file for reading and writing
fstream iofile("file.dat",ios::in|ios::out) ;

// Read in (fictitious) file header
FileHeader hdr ;
iofile >> hdr ;

// Store current location of stream 'get()' pointer
streampos marker = ifs.tellg() ;

// Read (fictitious) file data object
FileDataObj fdo ;
iofile >> fdo ;

// modify file data object

// Move current' location of stream
// 'put (')' pointer to marked position
ifs.tellp(marker) ;

// Write modified object over old location in file
iofile << fdo ;
```

264

Streaming custom classes

- You can **stream custom classes** by defining your matching `operator<<()`, `operator>>()` for those classes
 - Standard Library stream classes implement operators `<<`, `>>` as member functions for streaming of all basic types
 - This is not an option for you as **you can't modify the Standard Library classes**
 - But in general, binary operators can be
 1. member of class `ostream(cout)`,
 2. member of your class, or
 3. be a global function.
 - Option 1) already ruled out
 - Option 2) doesn't work because class being read/written needs to be *rightmost* argument of operator, while as a member function it is by construction the *left* argument of the operator
 - Option 3) works: **implement operator<< as global operator**

© 2006 Wouter Verkerke, NIKHEF

265

Streaming custom classes

- For types that can be printed on a single line, overloading the operator<<, operator>> is sensible
 - Class string obvious example

```
String s("Hello") ;  
cout << string << " World" ;
```

```
String s("Hello") ;  
cout.operator<<(operator<<(cout,string),"World") ;
```

- For classes that read/write multi-line output, consider a separate function
 - operator>>,<< syntax for such cases potentially confusing: processing white space etc traditionally handled by stream not by operator
 - Example names: `readFromStream()`,`writeToStream()`

266

Implementing your own <<,>> operators

- Important: operators <<,>> need to return a reference to the input `ostream`, `istream` respectively
 - Essential for ability to chain << operations

```
cin >> a >> b ;  
cout << a << b << c ;
```

- Example implementation for class string

```
ostream& operator<<(ostream& os, const String& s) {  
    os << s._s ;  
    return os ;  
}
```

```
istream& operator>>(istream& is, String& s) {  
    const int bufmax = 256 ;  
    static char buf[256] ;  
    is >> buf ;  
    s = buf ;  
    return is ;  
}
```

Note: no const here
as String is modified
