

# Timescans for run5: Preliminary results with 4D tracking optimisation in LHCb

# The VELO detector – schematic

Front view of two modules

Pérez, Daniel & Neufeld, Niko & Núñez, Agustín. (2022). Search by triplet: An efficient local track reconstruction algorithm for parallel architectures.

Preliminary change for Upgrade 2 (U2): 26  $\rightarrow$  32 stations

# The VELO detector – schematic(er)

- NOTE: Modules are NOT perfectly aligned in reality (purposefully)
- HOWEVER, the above is "good enough" for this presentation

# Metadata of runs

- 20000 events with ~50M MCPs produced
- No encoding or decoding: every fired pixel counted as hit
  - **Clustering not yet available** (coming very soon)
  - 4D Spacepoints directly used

# One slide overview of LHCb tracking

## 1. START

$i\text{ModPair} - 2$   $i\text{ModPair} - 1$   $i\text{ModPair}$   $i\text{ModPair} + 1$

## 2. SEEDING

$i\text{ModPair} - 2$   $i\text{ModPair} - 1$   $i\text{ModPair}$   $i\text{ModPair} + 1$

## 4. SEEDING

$i\text{ModPair} - 1$   $i\text{ModPair}$   $i\text{ModPair} + 1$   $i\text{ModPair} + 2$

## 3. FORWARDING

$i\text{ModPair} - 1$   $i\text{ModPair}$   $i\text{ModPair} + 1$   $i\text{ModPair} + 2$

# Efficiencies, ghosts and clones

3D = Out Of The Box

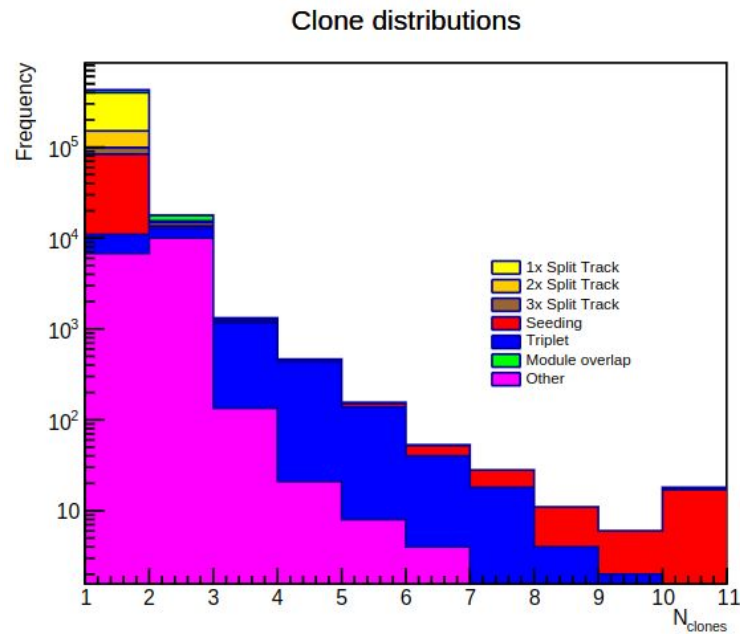

|            | Run 3 Baseline<br>(Forward) | Run 5 3D<br>(Forward) | Run 5 3D<br>(Backward) |
|------------|-----------------------------|-----------------------|------------------------|
| Efficiency | 98.32%                      | 98.69%                | 97.31%                 |
| Ghost Rate | 2.12%                       | 3.24%                 | 2.50%                  |
| Clone Rate | 2.87%                       | 10.31%                | 2.30%                  |

**Remember ×10  
occupancy!**

Very high clone rate...  
also asymmetrical?

# Clone rates 3D Algorithm in run5

→ There are MANY once-split Split Track Clones!

# Different types of clones

## 1. Split Track Clones: Leading Order (LO)

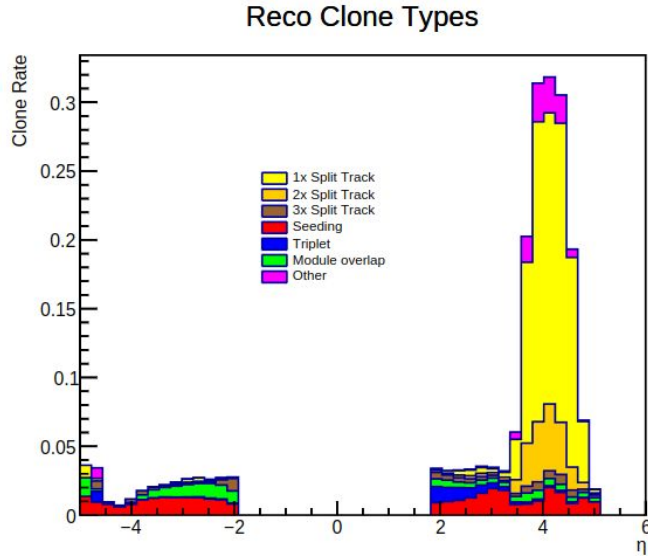

8 hit (MC) track

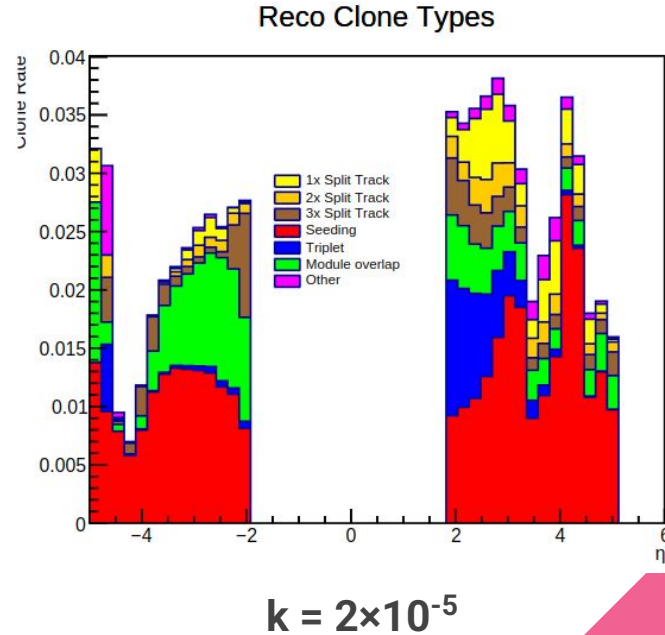

# Clone rates with deflection z-dependence (still 3D)

Out of the box

Max Deflection =  $\mathbf{k} \times \Delta \mathbf{z}^2$

# Time based cuts on seeding and forwarding

- Kalman filter: Estimate + Measurement weighted together
- Measurement must lie within specified range of readout resolution
  - How much?
  - Starting point:  $3\sqrt{2}\sigma$  in seeding, in forwarding  $3(1 + 1/N_{hits})^{\frac{1}{2}}\sigma$
  - Based on simple error propagation (backup slides). Best choice?

# Forward efficiency and fake rate wrt pixel time resolution

1x describes the standard windows from before

# Algorithm tweaks compared with time cuts (50ps, 1x)

| <b>FORWARD</b> | Run 3 Baseline | Run 5 3D | Run 5 3D ( $z^2$ ) | Run 5 4D ( $z^2$ ) |
|----------------|----------------|----------|--------------------|--------------------|
| Efficiency     | 98.32%         | 98.69%   | 98.27%             | 98.86%             |
| Ghost Rate     | 2.12%          | 3.24%    | 4.40%              | 2.58%              |
| Clone Rate     | 2.87%          | 10.31%   | 2.90%              | 3.54%              |

No forward/backward distinction in Run 3 benchmarks!

| <b>BACKWARD</b> | Run 3 Baseline | Run 5 3D | Run 5 3D ( $z^2$ ) | Run5 4D ( $z^2$ ) |
|-----------------|----------------|----------|--------------------|-------------------|
| Efficiency      | 98.32%         | 97.31%   | 96.87%             | 98.11%            |
| Ghost Rate      | 2.12%          | 2.50%    | 2.86%              | 1.62%             |
| Clone Rate      | 2.87%          | 2.30%    | 2.27%              | 2.28%             |

Why does clone rate get worse only for forward?

# Timescans: What about other resolutions?

Important note: This is for regular 1x time window!

Forward Efficiency, Ghost Rate, and Clone Rate vs Time Resolution

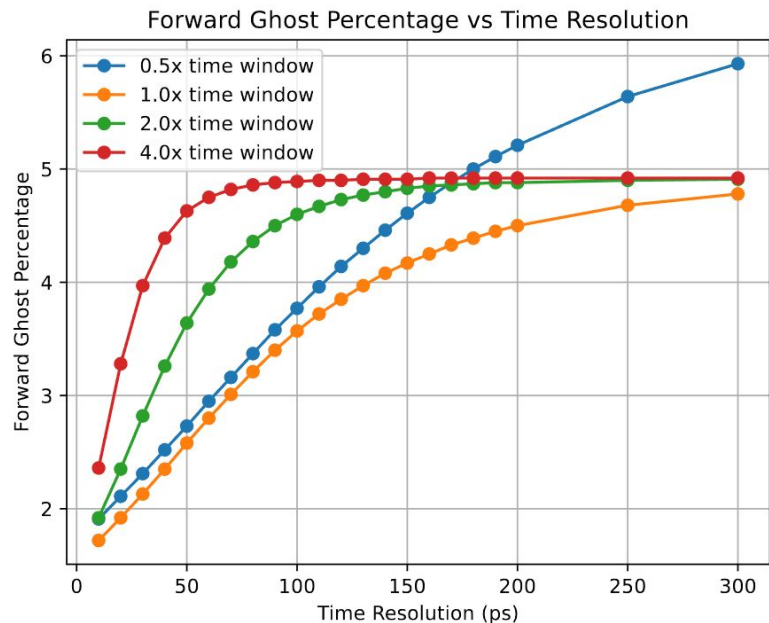

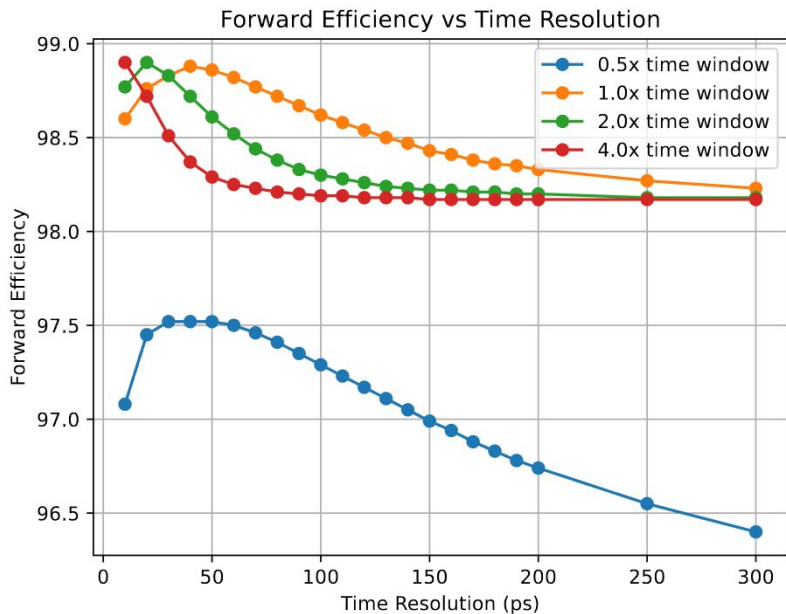

Backward Efficiency, Ghost Rate, and Clone Rate vs Time Resolution

# Timescans: What about other resolutions?

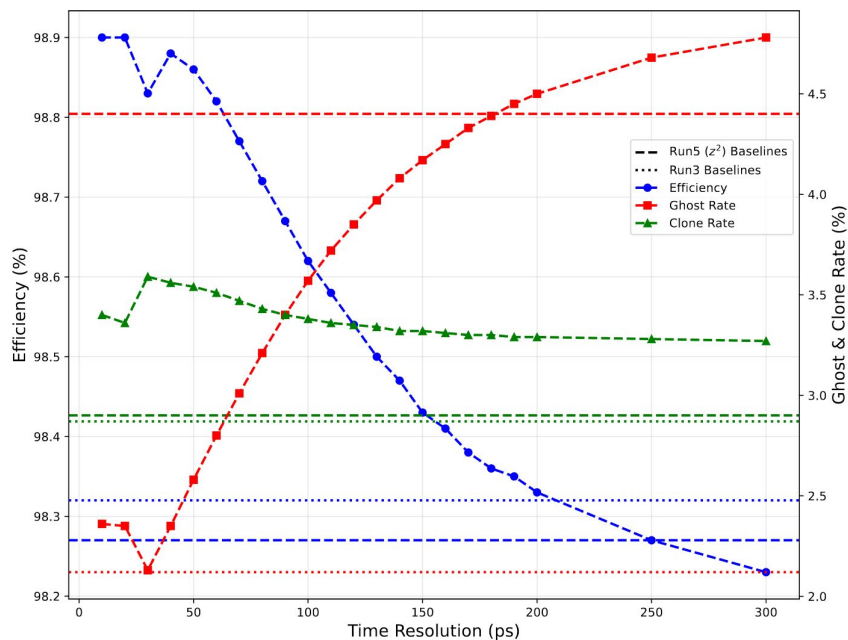

Recall:

# Timescans: What about other resolutions?

Now for the “best” efficiency of the four windows

Forward Efficiency, Ghost Rate, and Clone Rate vs Time Resolution

Backward Efficiency, Ghost Rate, and Clone Rate vs Time Resolution

# Outlier timestamps

Problem: Clone rates too high

→ Potential solution: Allow up to 1 (or more) hits in a track that are outside of nominal cut

But before we move on, let's have brief look what the time scatter plots tell us...

Do we expect many hits to fall outside of our cut?

# Outlier Timestamps – Forwarding

$\Delta t$  scatter for forwarded hits (norm, forward)

$\Delta t$  scatter for forwarded hits (norm, backward)

# Outlier Timestamps – Forwarding

Skews – why?

Speed assumed to be exactly  $c$ !

$$t_{next}^{pred} = t_{curr} + \Delta r / c < t_{next}^{meas}$$

Options:

- Skip outliers
- Widen forwarding window
- Scale prediction by skew

$\Delta t$  scatter for forwarded hits (norm, forward)

$\Delta t$  scatter for forwarded hits (norm, backward)

# Last but not least: Throughput

Ensure around 1min of runtime at least. Repeat 5x for each algorithm configuration to ensure no outlier.

- For run3:
  - 500 events
  - 10k repetitions on L40s, 2k on V100
- For run5:
  - 100 events
  - 2k repetitions on L40s, 400 on V100

# Last but not least: (preliminary) Throughput

All numbers given are in kHz of Events

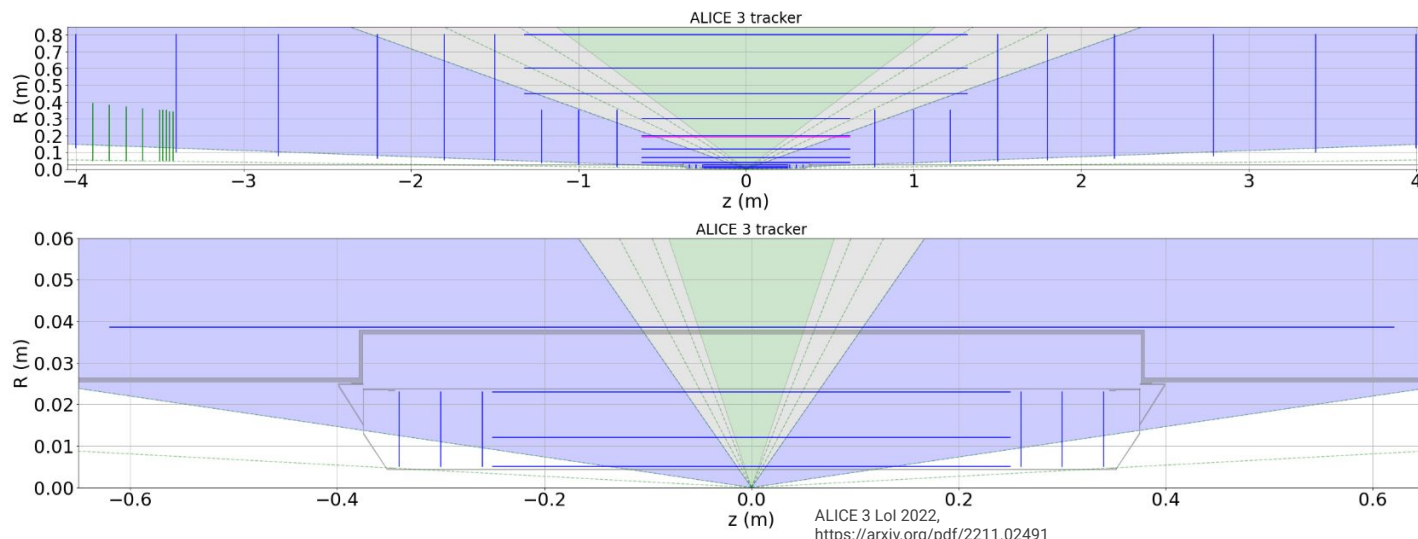

|      | Run3 | Run5 3D | Run5 3D ( $z^2$ ) | Run5 4D ( $z^2$ ) |
|------|------|---------|-------------------|-------------------|
| L40s | 1560 | 98      | 77                | 70                |
| V100 | 600  | 39      | 25                | 21                |

Unreasonable drop with  $z^2$  dependence!

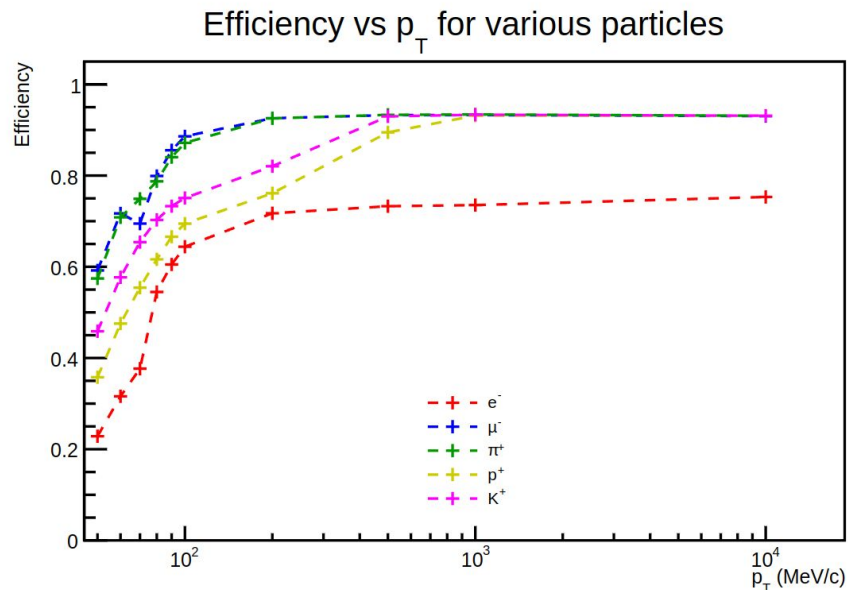

# Going forward from forward: Central rapidities in ACTS

- LHCb: Forward detector
- ALICE 3: Barrel & endcap detector
- ACTS: General tracking framework
  - Shift focus to more central region

ALICE 3 geometry implementation in ACTS ongoing!

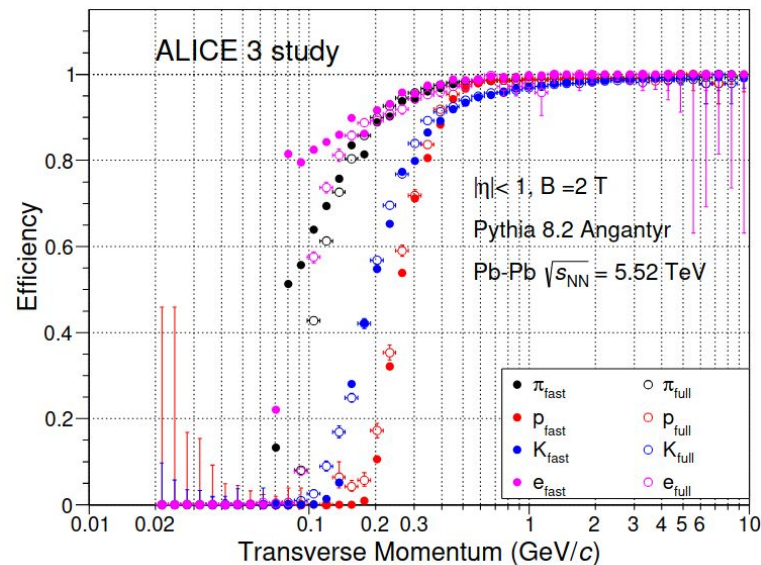

# ACTS ALICE 3 Efficiency status (spoiler: terrible)

Material interactions?  
Seeding? Geometry?

Lol reference

# Conclusions & Going forward

- LHCb results:
  - Introducing simple 1D filtering and cutting on time
    - Improves Efficiency slightly
    - Reduces ghost rate by 40%
    - Increases clone rate by 20%
  - Throughput remains reasonable with increased occupancy
  - Clone rate expected to drop with introduced clustering
  - Minor tweaks possible (outliers, skew correction)
  - Establish systematic error bands
- Moving forward: ACTS
  - Establish baselines and recreate Lol results
  - Move to very low  $p_T$  spectrum

# BACKUP SLIDES

# Tracking in Allen: Search By Triplet

- Example case:

# Error propagation...

$$\sigma_{\mu} = \frac{\sigma}{\sqrt{N}}$$

Forwarding: Standard error on the mean:

$$\sigma_{\mu,next} = \sqrt{\sigma_{\mu,curr}^2 + \sigma_{meas}^2} = \sqrt{\sigma^2/N_{Hits} + \sigma^2} = \sigma \sqrt{1/N_{Hits} + 1}$$

# Tracking in Allen: Search By Triplet

$i\text{ModPair} - 2$

$i\text{ModPair} - 1$

$i\text{ModPair}$

$i\text{ModPair} + 1$

- First: Create set of triplets starting in last layer.

# Tracking in Allen: Search By Triplet

$i\text{ModPair} - 2$     $i\text{ModPair} - 1$     $i\text{ModPair}$     $i\text{ModPair} + 1$

- First: Create set of triplets starting in last layer. Then repeat following:
  - a. Move to next module pair

# Tracking in Allen: Search By Triplet

$i\text{ModPair} - 1$     $i\text{ModPair}$     $i\text{ModPair} + 1$     $i\text{ModPair} + 2$

- First: Create set of triplets starting in last layer. Then repeat following:
  - Move to next module pair
  - Forward existing tracks and tag hits as used

# Tracking in Allen: Search By Triplet

$i\text{ModPair} - 1$      $i\text{ModPair}$      $i\text{ModPair} + 1$      $i\text{ModPair} + 2$

- First: Create set of triplets starting in last layer. Then repeat following:
  - Move to next module pair
  - Forward existing tracks and tag hits as used
  - Create seeds with remaining hits in layer

# Tracking in Allen: Search By Triplet

$i\text{ModPair} - 1$      $i\text{ModPair}$      $i\text{ModPair} + 1$      $i\text{ModPair} + 2$

- First: Create set of triplets starting in last layer. Then repeat following:
  - a. Move to next module pair
  - b. Forward existing tracks and tag hits as used
  - c. Create seeds with remaining hits in layer
- And so on...

# Outlier timestamps – Seeding

Simple idea: Allow for up to 1 (or more) hits in a track that are outside of nominal cut

5000 events

No noticeable  
deviation in  
seeding

$3\sqrt{2}\sigma$  is plenty

# Outlier timestamps: Forwarding 2D

$\Delta t$  scatter vs module ID for all forwarded hits

# Clone rates – Why the increase at all? Speculation...

## 1. Split Track Clones: Leading Order (LO)

8 hit (MC) track

# Clone rates – Why the increase at all? Analysis

# Clone Diagnosis – Rates wrt $\eta$

Max Deflection =  $k \times \Delta z^2$ ,  $k = 2 \times 10^{-5}$

With time cuts included

Reco Clone Types

Reco Clone Types

# Clone Diagnosis – Number of clones per MC particle

$$\text{Max Deflection} = k \times \Delta z^2, k = 2 \times 10^{-5}$$

With time cuts included

Clone distributions

Clone distributions

# Clone Diagnosis – What are we dealing with here?

Clone Rate by number of MCP hits

- Increase dominated by "Other" clone type
- By OOM, dominated by single clones
- No clear MC track length correlation
  - Slight overrepresentation in 8-10 hit region

# Clone Diagnosis – Number of hits of MCP

Hit distribution of MCPs with at least one clone

Hit distribution of all MCs

# Different types of clones

1. Split Track Clones
2. Seeding Clones
3. Module Overlap Clones
4. Triplet Clones
5. Other Clones

# Different types of clones

## 1. Split Track Clones

8 hit (MC) track

# Different types of clones

## 1. Split Track Clones: Leading Order (LO)

8 hit (MC) track

# Different types of clones

## 1. Split Track Clones: Next to Leading Order (NLO)

a. One extra, missing, or overlap

8 hit (MC) track

# Different types of clones

## 1. Split Track Clones: Next to Next to Leading Order (NNLO)

- a. Two extra, missing, or overlap (any combination possible)

8 hit (MC) track

# Different types of clones

1. Split Track Clones
2. Seeding Clones

Hits at certain  $\phi$ :

- $i\text{ModPair} - 1$ : 1
- $i\text{ModPair}$ : **MANY**
- $i\text{ModPair} + 1$ : 1

$i\text{ModPair} - 1$      $i\text{ModPair}$      $i\text{ModPair} + 1$      $i\text{ModPair} + 2$

# Different types of clones

1. Split Track Clones
2. Seeding Clones

iModPair - 1    iModPair    iModPair + 1    iModPair + 2

# Tracking in Allen: Search By Triplet (SBT)

- Input: Clusters
  - $x, y, z, t, ID$
- Clusters sorted by  $\phi$  per module

# Tracking in Allen: Search By Triplet

- Sweep through detector from back
- First: Create set of triplets starting in last layer. Then repeat following:
  - a. Move to next module pair
  - b. Forward existing tracks and tag hits as used
  - c. Create seeds with remaining hits in layer

# Hit density wrt modules

Hit Density

No clear forward/backward preference

# ACTS Truth Seeding efficiency

# ACTS D0 resolution

$D_0$  resolution vs  $\eta$  for muon
