

Cosmology & Dark Matter

BND Graduate School 2017
12th Sep 2017

Christoph Weniger
University of Amsterdam

Outline

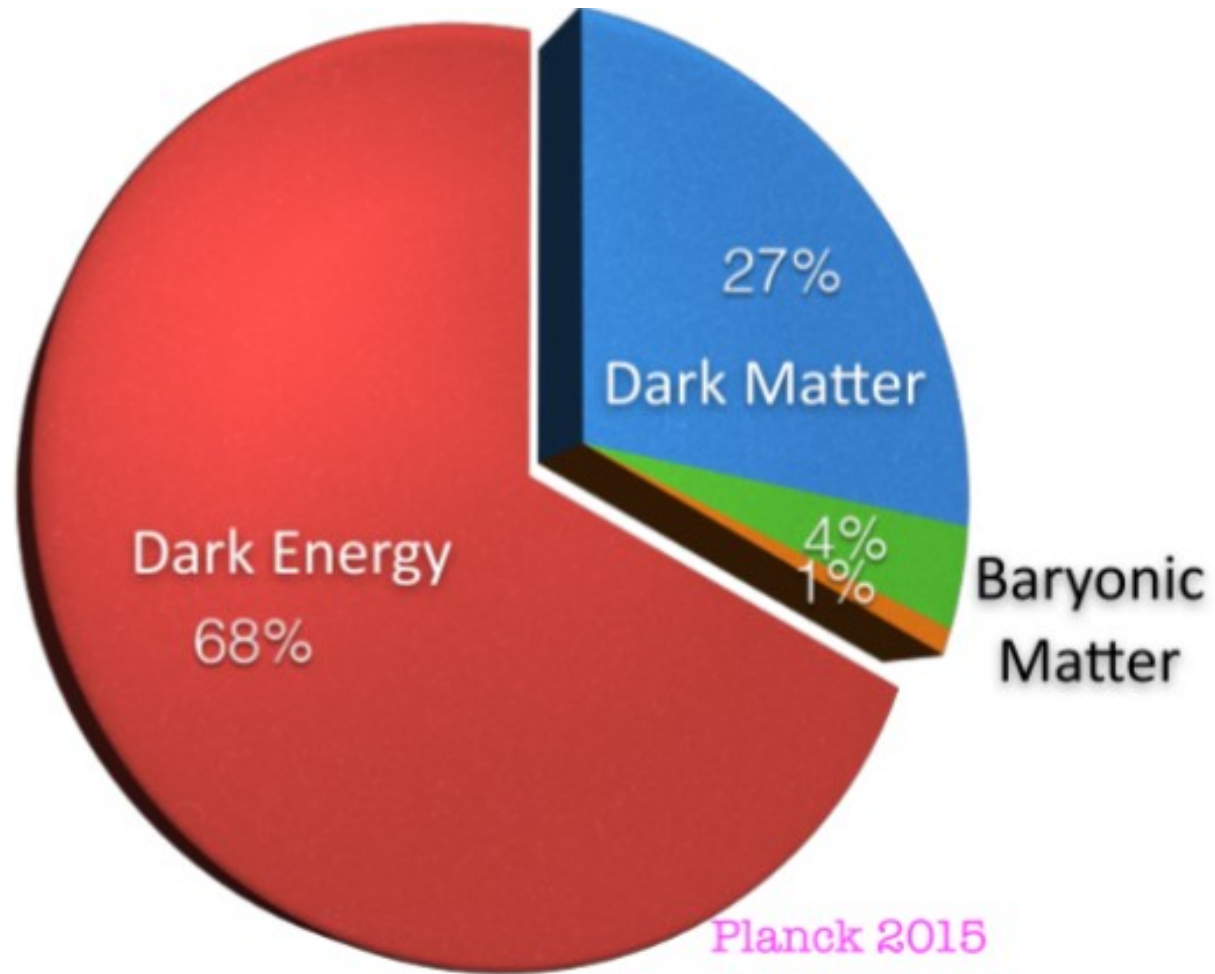

Lecture 3 – The non-linear Universe, dark matter and MOND

- Evidence for dark matter
- N-body simulations of CDM
- CDM problems and solutions
- Status of Modified Newtonian Dynamics (MOND)

Lecture 4 – Searches for particle dark matter

- Properties of dark matter & dark matter production
- Dark matter candidates & Searches
- Indirect searches for dark matter
 - Signal characteristics
 - Searches with cosmic rays
 - Searches with photons
 - Signal hints and challenges

Our Universe

Evidence for dark matter in the Universe

Towards N-body simulations

Situation

- The Milky Way halo has of the order of 10^{67} particles (assuming a DM mass of 1 GeV)
- They do not directly interact, but only via their combined gravitational potential
- We are interested in the **time-evolution of the distribution function** of DM particles in the non-linear regime

$$f(\mathbf{x}, \mathbf{v}, t)$$

- The dynamics is described by the **Poisson-Vlasov** equation:

$$\nabla^2 \Phi(\mathbf{x}, t) = 4\pi G \int d^3v f(\mathbf{x}, \mathbf{v}, t)$$

$$\frac{df}{dt} = \frac{\partial f}{\partial t} + \frac{\partial f}{\partial \mathbf{x}} \mathbf{v} + \frac{\partial f}{\partial \mathbf{v}} \left(-\frac{\partial \Phi}{\partial \mathbf{x}} \right) = 0$$

Monte Carlo Approach

Why Monte Carlo

- Discretization of distribution function in 6-dim phase space is computationally way too extensive (need to resolve a very large range of scales)
- Solution: Instead, sample “test particles” from distribution function, and track their motion

Equation of motion for individual particle

$$\ddot{\mathbf{x}}_i = -\nabla_i \Phi(\mathbf{x}_i)$$

Gravitational potential generated by test particles

$$\Phi(\mathbf{x}) = -G \sum_{i=1}^N \frac{m_j}{[(\mathbf{x} - \mathbf{x}_i)^2 + \epsilon^2]^{1/2}}$$

Notes

- Mass of “test particles” usually exceeds solar mass
- Softening required to remove individual particle collisions
- Up to recently, most simulations where “dark matter only”, i.e. the effects of baryons is not included

Aquarius MW halo simulations

zoom-in simulations of an individual
Milky Way-like DM halo:
different resolution levels

Springel+ 2008

Radial profile of relaxed DM halos

DM halos have a nearly universal
spherically averaged density profile:
-1 to -3 logarithmic slope

very well converged

Fitting functions to DM profile

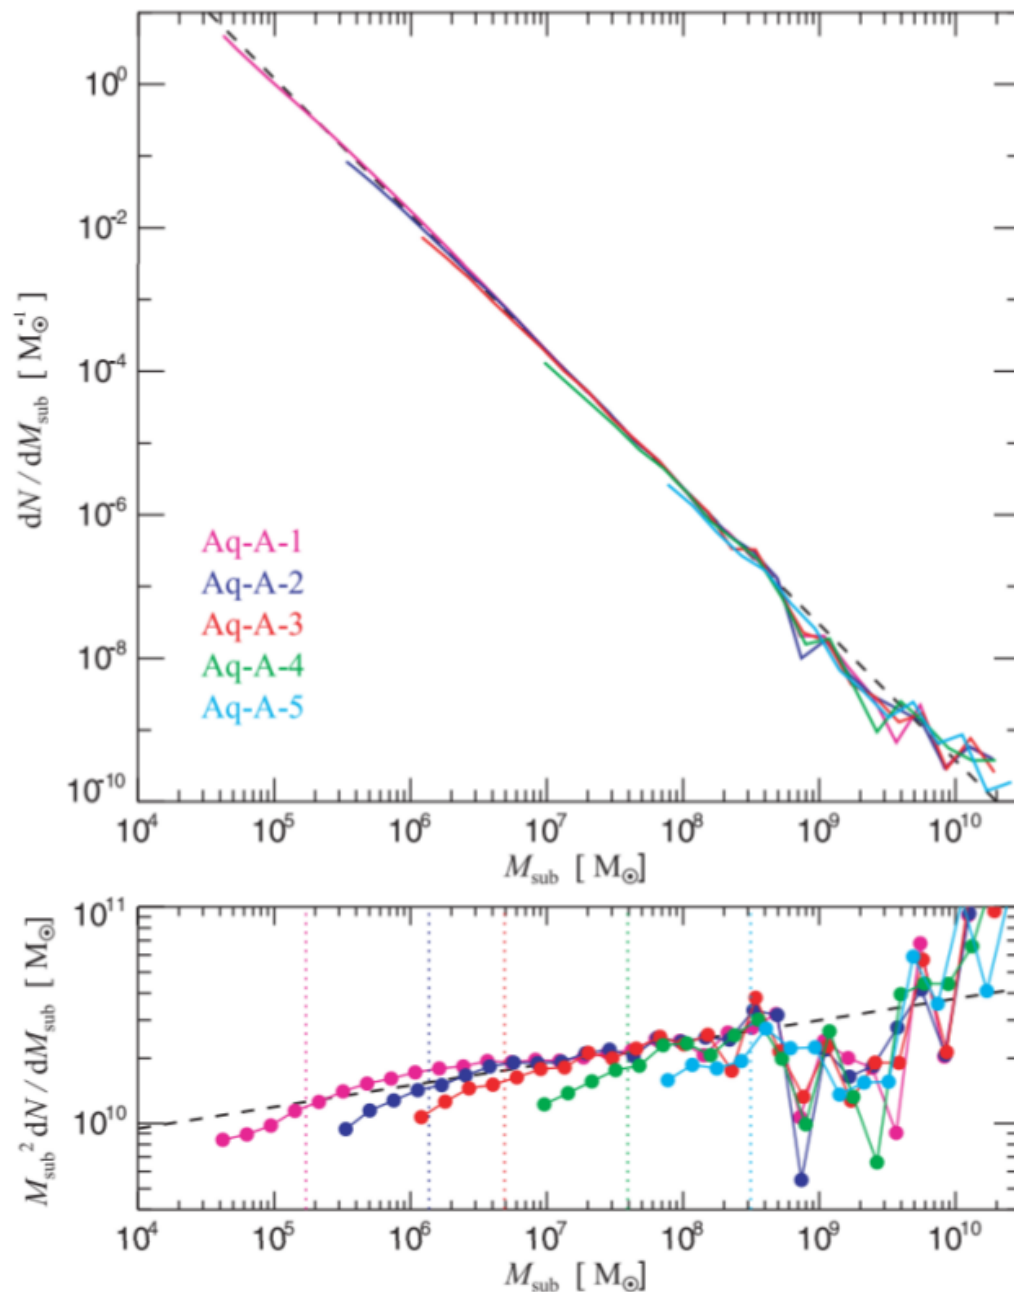

NFW:

$$\rho(r) = \frac{\rho_s}{(r/r_s)(1 + r/r_s)^2}$$

Einasto:

$$\ln[\rho(r)/\rho_{-2}] = (-2/\alpha)[(r/r_{-2})^\alpha - 1]$$

Subhalo distribution function

subhalo mass function has a slope close to -2; slightly shallower; extrapolate → annihilation boost

$$\frac{dN}{dM_{\text{sub}}} \propto M_{\text{sub}}^{-2+\epsilon}$$

Springel+ 2008

Credit: M. Vogelsberger

Velocity distribution of DM

sample of six different halos: all have individually different local DM velocity distributions

DM 'Astronomy'?

This is often approximated by a truncated Maxwellian

$$f(v) \propto v^2 e^{-\frac{3}{2} \frac{v^2}{v_{\text{rms}}^2}} \Theta(v - v_{\text{esc}})$$

("Standard halo model")

For the Milky Way

$$v_{\text{rms}} \sim 270 \frac{\text{km}}{\text{s}} \quad v_{\text{esc}} \sim 540 \frac{\text{km}}{\text{s}}$$

Modified Newtonian Dynamics (MOND)?

See: Famaey & McGaugh 2012

M. Milgrom (1983)

Idea

- At very small *accelerations*, Newton's Law is modified (increase "inertia")

$$F_N = ma \rightarrow F = m \frac{a^2}{a_0} \quad a_0 \simeq 10^{-8} \text{ cm/s}^2 \sim H_0$$

- Gravity part unchanged

$$F_{\text{gravity}} = \frac{GMm}{r^2}$$

- This can also account for flat rotation curves

$$\begin{aligned} F_{\text{gravity}} = F_N \quad \& \quad a = \frac{v^2}{r} \quad \Rightarrow \quad \frac{GMm}{r^2} = m \frac{a^2}{a_0} = \frac{mv^4}{a_0 r^2} \\ \Rightarrow \quad v &= (GMa_0)^{1/4} \end{aligned}$$

- MOND is only non-relativistic, so it cannot be tested on cosmological scales (e.g. gravitational lensing). It is an effective prescription, not a full theory.
- However, TeVeS (tensor vector scalar; J. Bekenstein, 2004) MOND generalization exists, which contains additional dynamical field. **It remains hard to reproduce all observations as cold DM does.**

Main argument *for* MOND

Tully-Fisher relation describes surprisingly tight correlation between the angular velocity of spiral galaxies and their **baryonic mass**.

MOND correctly accounts for

- normalization and
- slope

of the correlation over four orders of magnitude in Galaxy mass.

CDM predicts the dashed line, *assuming that all baryons associated with a DM halo are observed*.

Many question: Can **baryonic feedback** during galaxy formation generate such a correlation?

CDM vs MOND

	Cold Dark Matter	Modified Newtonian Dynamics
CMB: Magnitude of fluctuations	yes	no*
CMB: Angular power spectrum	yes	no*
Baryon acoustic oscillations in galaxy distribution	yes	no*
Bullet cluster (DM / gas segregation)	yes	no*
Spiral galaxy rotation curves	yes	yes
Tully-Fisher	maybe**	yes
Faber-Jackson	maybe**	yes
Simultaneous explanation of DM in dwarf galaxies and clusters	yes	maybe

*could work in more complete theories of MOND that introduce new fields that “act like DM” for cosmological purposes, or by adding *some* DM

** impact of baryons in galaxy formation is difficult to simulate a priori

What we know about dark matter

About 80 years after the first discovery of dark matter by Fritz Zwicky and others, we can now bracket its particle mass to within 80 orders of magnitude.

Uncertainty principle
(if DM is bosonic)

Hu+ 2000

MACHO searches
(massive compact
halo objects)

$$10^{-22} \text{eV} \lesssim m_{\text{DM}} \lesssim 10^{50} \text{GeV}$$

Tisserand+ 2007

Up to now, there are only various upper and lower limits:

cold:
negligible velocity dispersion

collisionless:
negligible self-interaction

weakly coupled:
negligible interaction with the rest of the world

What we know about dark matter

1. Has gravitational interactions and is (meta-)stable.
2. DM seems to be dark, i.e. is not observed to interact with light.
3. DM must be nearly dissipationless
4. DM cannot have large self-interaction (though existing limits are very weak).
5. The DM mass is only constrained to within some ~ 80 orders of magnitude.
6. DM must be cold or (luke-)warm
7. Particle DM candidates require physics beyond the Standard Model.

Dark matter is really “dark”

Strong constraints on a “milli-charge” of dark matter particles.

Electric charge of DM compared to electron charge

Candidates for particle dark matter

Mass-scales and interactions are suggested by

- Theoretical arguments → Various incarnations of **WIMPs**, **Sterile neutrinos**, **Axions**, ...
- Hints in the data → **positron excess**, **511 keV line**, **Fermi GeV excess**, **PeV neutrinos**, ...

E-K Park 2007

Dark matter relics

Boltzmann equation for particles in comoving volume

$$\frac{dN_X}{dt} = -s\langle\sigma v\rangle \left[N_X^2 - (N_X^{\text{eq}})^2 \right]$$

$$N_X \equiv n_X/s, \quad x \equiv \frac{M_X}{T}$$

Relic density today

$$\Omega_X = \frac{\rho_{X,0}}{\rho_{\text{crit},0}} = \frac{M_X N_X^\infty s_0}{\rho_{\text{crit},0}}$$

“WIMP miracle”

$$\Omega_X h^2 \sim 0.1 \frac{3 \times 10^{-26} \text{cm}^3 \text{s}^{-1}}{\langle\sigma v\rangle} \sim \frac{10^{-3} G_F}{\langle\sigma v\rangle}$$

Lee & Weinberg (1977) bound

Two solutions for CDM, one on each side of the Z-resonance:

$$\sigma \simeq G_F^2 m_\chi^2 \text{ thus } \Omega_\chi h^2 \simeq (\text{GeV}/m_\chi)^2 \text{ and } \sigma \simeq g_w^4/m_\chi^2 \text{ thus } \Omega_\chi h^2 \simeq (m_\chi/\text{TeV})^2$$

For 4th. gen. active neutrinos, $m < m_Z/2$ forbidden by LEP-but similar for other models

Completely different: Misalignment mechanism

$T \sim f_a$ (very early universe)

- $U_{PQ}(1)$ spontaneously broken
- Higgs field settles in “Mexican hat”
- Axion field sits fixed at $a_i = \Theta_i f_a$

$T \sim 1 \text{ GeV}$ ($H \sim 10^{-9} \text{ eV}$)

- Axion mass turns on quickly by thermal instanton gas
- Field starts oscillating when $m_a \gtrsim 3H$
- Classical field oscillations (axions at rest)

Axions are born as nonrelativistic, classical field oscillations
Very small mass, yet cold dark matter

Election of Richard Nixon

Neutralino abundance

Neutralino LSP relic abundance

- LSP = \tilde{B} (typical in CMSSM) is OVERDENSE
(σ_{annih} into $f\bar{f}$ through \tilde{f} exchange is helicity suppressed $\sim m_f$)
- LSP = \tilde{H} and \tilde{W} (not GU, AMSB) is UNDERDENSE
unless $m \simeq TeV$ (large σ_{annih} into W^+W^- , ZZ , or $f\bar{f}$)
- RIGHT ABUNDANCE requires a special condition
 - Mixed composition (in CMSSM: “focus point”),
 - pole enhancement of σ_a ($m_\chi \simeq m_A/2$: “A-funnel region”- CP-odd Higgs A)
 - “coannihilation” between the LSP and the NLSP (Next to LSP- stop or other squarks)

Self-annihilation cross-section in CMSSM

Red \tilde{t}_1 co-annihilation

Orange A/H funnel

Yellow $\tilde{\chi}_1^\pm$ co-annihilation

Particle spectrum of best-fit point

Best-fit point of stop coannihilation region of the CMSSM
