

Oscillation study with 1 line

Quick look

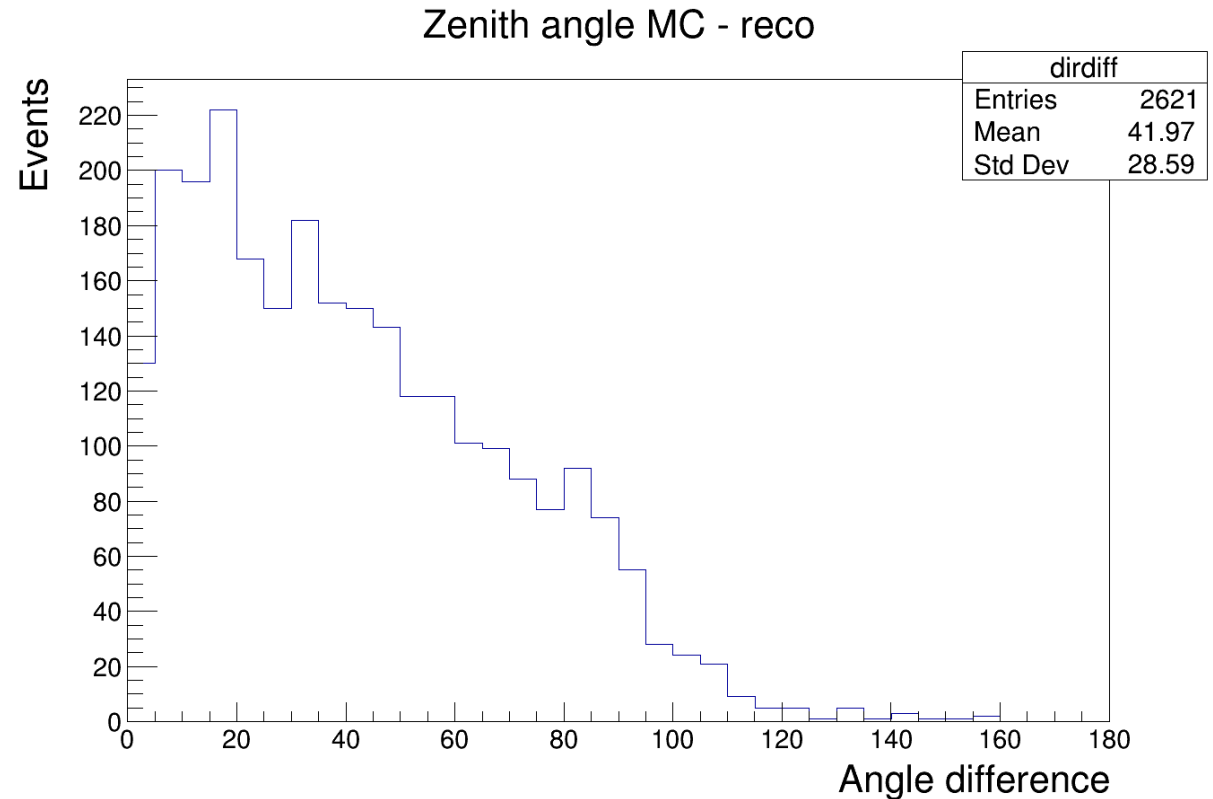

Expected events with and without oscillation with 1 ORCA line (ideal energy resolution)

rate/yr/DU (5 trigdoms)

What sort of angle resolution can one expect?

- Run track reco chain on ORCA 1 DU MC
- Event selection: closer than 40m in XY
- ≥ 4 DOMs in trigger
- < 45 deg from up

Can the energy be estimated with one line?

- Nothing from the track reco (J_{energy} , J_{start}). Possibly wrong input parameters?
- Alternative: correlation

$$n_{\text{hits}} \sim E * \cos_{\text{zenith}}/\text{distance}$$

$N_{\text{hits}} \sim E * \cos_{\text{zenith}}/\text{distance}$, MC data

- Energy from MC
- Zenith from MC
- Distance from MC

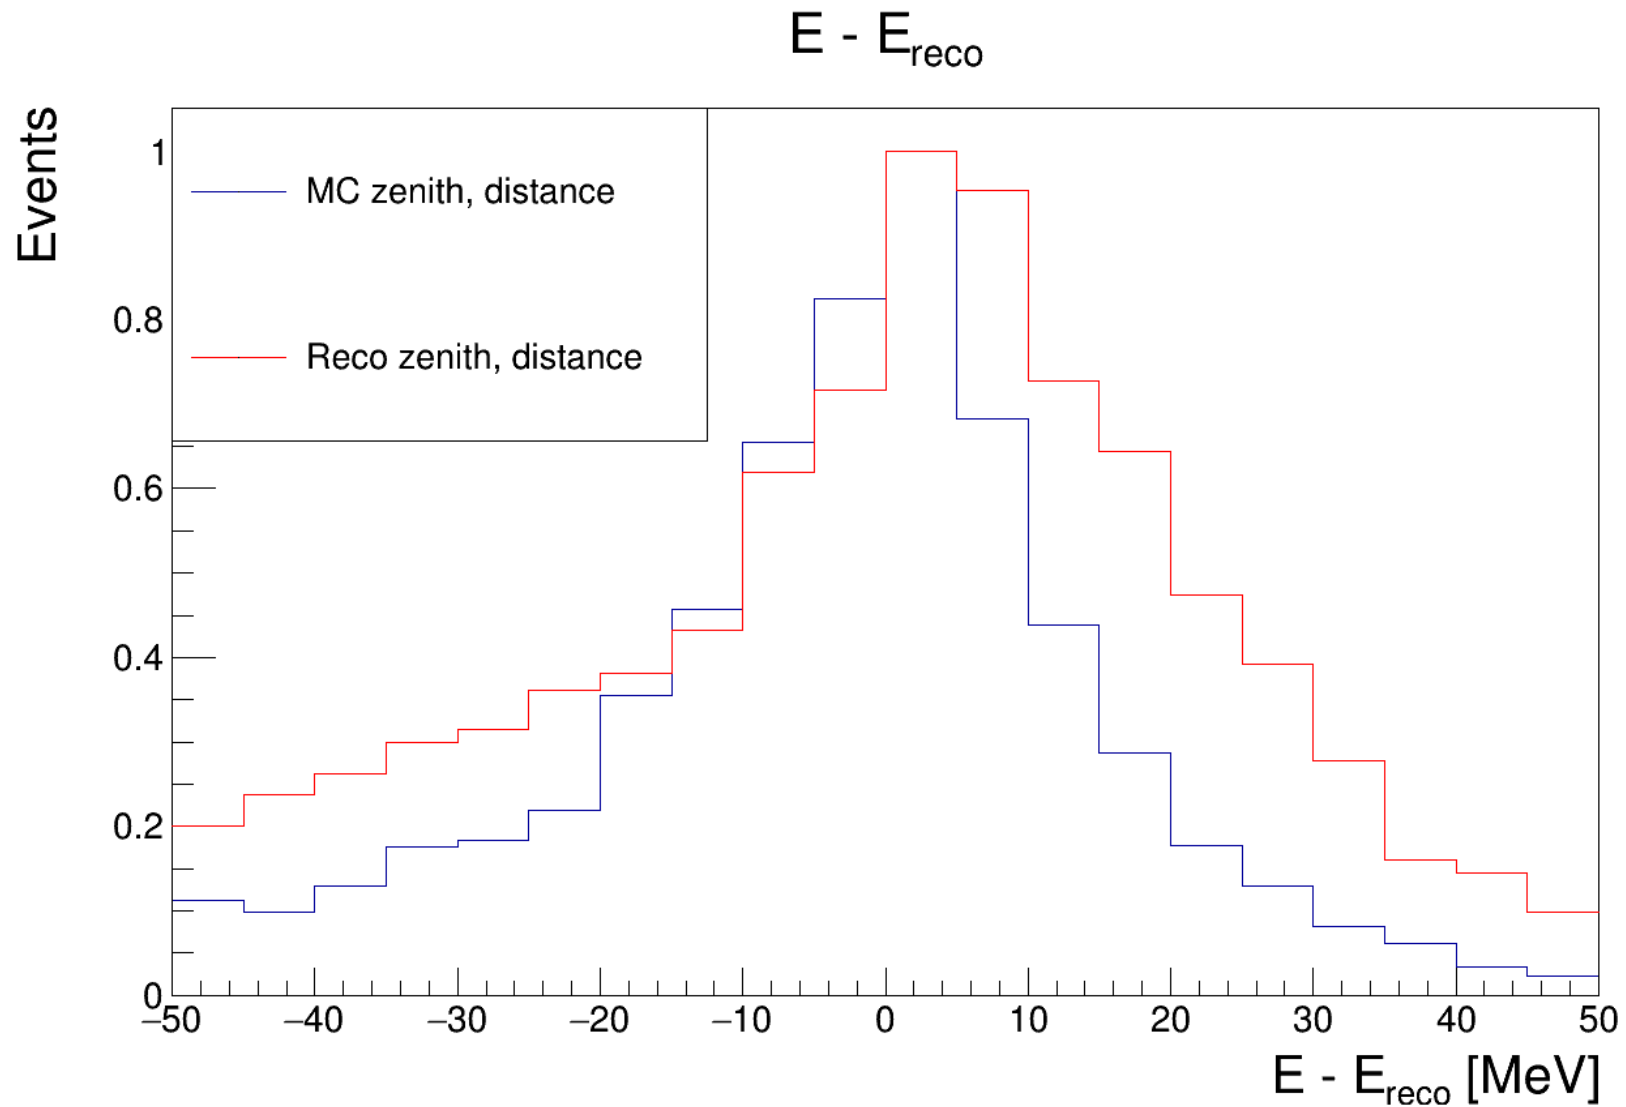

nhits vs $E \times \cos_{\text{zenith}}/\text{distance}$, MC

nhits vs $E \times \cos_{\text{zenith}}/\text{distance}$, MC

Repeat this with zenith and position from reconstruction

Conclusions/discussion

- A very approximate energy can be obtained
- Can the angle resolution be improved?
- Is there a better way to estimate the energy?
- Might be easier to integrate over energy/angle and only do muon counting.
